Abstract

Contemporary public discourse often raises concerns that migration may threaten social stability, fueling support for exclusionary integration policies. We study this issue by estimating the causal effect of China's recent reform of its internal migration institutions on labor unrest (e.g., strikes). Exploiting variation from the reform's population-based discontinuity rule, we find that the reform significantly reduced labor unrest. A key mechanism is migrants' enhanced settlement intentions: to secure the opportunity of settlement offered by the reform, migrants have weaker incentives to engage in unrest. We show that the reform increased the likelihood of migrants remaining in migration destinations, and through a novel causal mediation analysis, we find that enhanced settlement intentions can explain 63 percent of the reform's effect on labor unrest. Moreover, the reform's effect on labor unrest is more pronounced in places where migrants live closer to their origins or are culturally similar to natives, making them more inclined to stay once the reform lowers institutional integration barriers. We find no evidence that the reform changed migrant composition, significantly improved migrants' wellbeing, or prompted governments to tighten social control.

1 Introduction

Migration is a central political and policy issue in many countries. Public discourse and policy debates often raise the concern that migration may undermine social stability. In the developing world, autocratic governments fear that massive rural-to-urban migrants can lead to population concentration in cities and threaten regime stability (e.g., Wallace, 2014). More broadly, in many developed countries today, immigration has triggered backlash among natives, who blame immigration as a source of social instability (Marie and Pinotti, 2024; Hangartner et al., 2019; Campante et al., 2023).¹ Such concerns fuel support for exclusionary integration policies, i.e., restricting migrants' rights in host societies, aiming to weaken migrants' ability to stay and to deter further migration.

However, it is not straightforward to assert the causal link between integration policy and social stability. On the one hand, existing concerns suggest that relaxing integration restrictions may attract more migrants and/or certain types of individuals who are more prone to social unrest (e.g., those with poorer labor market opportunities). Yet, the quantity and compositional effects are fundamentally empirical questions, and consequently, how the policy change affects social stability is ambiguous. Relatedly, the existing literature does not detect out-of-control chain migration following immigrant legalization, and the literature has mixed findings on the effect of immigration on crime.² On the other hand, reduced integration barriers give migrants hope to settle in host societies. The enhanced settlement intention may weaken migrants' incentive for engagement in social unrest, as they now depend on the government of the host society to grant their ultimate settlement. This is in spirit similar to the manner that longer intended migration duration increases migrants' investments in assimilation (e.g., Dustmann, 2008; Adda et al., 2022). Taken together, it remains an open question as to how changes in integration policy affect social stability.

To help answer this question, we study internal migration in China. China is an intriguing setting to study the relationship between integration policy and social stability. China's institutions governing internal migration share similarities with those governing international migration elsewhere (Chan, 2019; Vortherms, 2023). In China, the household registration (*hukou*) system ties each individual to a registration location. Much like nationality determines the country in which one enjoys the full citizenship rights, the *hukou* registration location determines *where* the individual can access public services (e.g., public education, healthcare, subsidized housing, and

¹Marie and Pinotti (2024) document that from 2017 to 2020, many people in OECD countries expressed concerns that immigrants increased crime rates, and in many countries, more people were concerned about the crime effects of immigration than about the unemployment effects. Hangartner et al. (2019) show that mere exposure to refugee arrivals induces lasting concerns about social turmoil caused by immigration (e.g., crime, terrorism, and burden on the country). Speaking to electoral consequences, Campante et al. (2020) show that during the 2014 US midterm elections, Republican members of Congress were more likely to connect the Ebola virus with immigration and terrorism in their newsletters and TV campaign ads, although Ebola had negligible impacts on American society.

²For instance, Spenkuch (2014) finds a small positive effect of immigration on crime in the US. In contrast, Ajzenman et al. (2023) report a null effect in Chile; however, they find that immigration leads to a (*mis-*)perception of increased crime.

social security).³ There are substantial institutional barriers to transferring registration across regions. This means that people often lose access to valuable public services when they leave their registration locations. Thus, although free movement is generally not restricted in contemporary China, migrants face substantial barriers to formal integration into their migration destinations, and migration tends to be temporary (Meng, 2012). For this reason, scholars often describe the *hukou* system as a “local citizenship” or an “internal passport” system, despite China being a unified country (Jin and Zhang, 2023; Au and Henderson, 2006).

To examine how the integration barriers associated with the *hukou* system affect social stability, we exploit a natural experiment generated by the nationwide reform of the *hukou* system in July 2014. This reform offered migrants an easier pathway to transfer their *hukou* to small- and medium-sized cities, gain access to local public services, and thus permanently relocate.⁴ We estimate the causal effect of this *hukou* reform on social stability using data from 2011 to 2019. Social stability is measured by labor unrest, which represents workers’ collective action to protest employers and demand public attention. This is a relevant proxy for migrants’ behaviors. A large literature on labor politics in China underscores that migrants have constituted the majority of participants in labor unrest in contemporary China (e.g., Lee, 2007; Chan, 2010; Friedman, 2014; Rho, 2023; among others). Meanwhile, the Chinese state is vigilant in monitoring and controlling labor unrest, despite the mostly apolitical nature of workers’ actions (Friedman, 2014), and the state has adopted various measures to prevent labor unrest from threatening regime survival.⁵ As a result, migrants have to weigh the benefits of unrest engagement against the costs of possible retaliation; the latter can encompass the losses from failing to seize settlement opportunities offered by the *hukou* reform.

Underpinning our research design is a population-based discontinuity rule that determines the reform status. The 2014 *hukou* reform only made it easier to transfer *hukou* into cities with less than 3 million population while maintaining strict restrictions in more populous cities. Exploiting this discontinuity in population, we implement a difference-in-discontinuity (DiDC) design, which combines difference-in-differences and regression discontinuity designs. In a nutshell, we estimate the causal effect of the reform by comparing the evolution in labor unrest between reform and non-reform cities around the 3 million population cutoff. Identification follows if the underlying trends vary smoothly across the reform cutoff, as in traditional regression discontinuity designs. We conduct a variety of exercises supporting the validity of our research design. First, the McCrary test shows no discontinuity in the density of the urban population at the 3 million cutoff, either before or after the reform. This suggests a lack of sorting into a specific reform status. Moreover, we do not detect abnormal population growth leading up to the reform. Second, we show that baseline characteristics vary smoothly across the 3 million cutoff. We consider a range of variables

³More details about the *hukou* system are in Section 2.1.

⁴Note that the reform merely reduced the barriers to getting a local *hukou*, but did not immediately grant migrants a local *hukou*. The reform still sets some (minimum) requirements that a migrant must satisfy in order to get a local *hukou*, including housing, employment, and enrollment in the local social security system. See Section 2.1 for more details.

⁵We provide a more detailed discussion of labor unrest in China in Section 2.2.

that may be associated with the dynamics of labor unrest, including the pretrends in labor unrest, lagged GDP growth, lagged fiscal expenditure growth (total, social security, and public security), as well as baseline economic and demographic variables. Third, through a careful review of Chinese policies, we do not detect any other policies that are correlated with population and may affect labor unrest. This ensures that our DiDC estimates would not wrongly pick up the influences of other policies. Finally, we find no evidence for anticipation of the reform.

Our main finding is that the *hukou* reform significantly *reduced* labor unrest. It reduced annual unrest by 1.419 incidents per million prime-age population (ages 25–54) between 2011 and 2019. This effect amounts to 42 percent of the mean level in non-reform regions. In addition, comparing to [Campante et al. \(2023\)](#), who estimate the causal effect of export slowdown on labor unrest in China, the reform's effect is equivalent to a \$3,576 increase in per-worker exports, about one standard deviation across Chinese prefectures.

We perform several tests to ensure that this effect is not a consequence of confounding factors related to the urban population or a statistical artifact. First, we conduct a placebo test that estimates the effects of the reform at other population cutoffs. The trends in labor unrest discontinuously vary only at the true cutoff of 3 million but not at other cutoffs, suggesting that our finding is not driven by confounders generally associated with population. Second, we find no evidence that non-governmental organizations can explain our results. Third, we show that the reform has no discernible effects on both the total population and urban population during the period we study, ruling out population growth as an explanation for our results. Fourth, as our measure of labor unrest is based on online information, we present evidence that our results are not driven by differential patterns in reporting local events, internet censorship, or self-censorship. Lastly, our results are not due to a natural reduction in protests against *hukou* policies. In fact, the majority of labor unrest events occur because of wage arrears and job displacement. The fraction of protests possibly against *hukou* policies is too small to account for our findings. In addition, we provide a variety of robustness tests, including alternative statistical inference, alternative specifications and estimators, exclusion of likely outliers, and covariate balancing. Our findings survive these tests.

We go on to carefully examine why the *hukou* reform reduced labor unrest. Our primary argument is that the *hukou* reform may enhance migrants' intentions to settle in their destinations, because it offers a previously unattainable opportunity of permanent settlement; as a result, migrants opt not to participate in labor unrest if they fear that government or employer retaliation may make them fail to secure the opportunity of permanent settlement. We present evidence consistent with this hypothesis. By analyzing an individual-level panel dataset with information on migration destinations, we show that migrants in a destination eligible for the *hukou* reform were significantly less likely to leave after the reform. This holds even when we control for origin fixed effects and interactions between individual characteristics and year dummies to account for economic factors that may drive migration decisions. These results suggest that migrants had stronger settlement intentions after the *hukou* reform.

Having established the link between the *hukou* reform and settlement intentions, we then formally quantify to what degree heightened settlement intentions can explain the reform's effect on labor unrest. To do so, we implement a novel causal mediation method. When estimating the treatment effect mediated by a mechanism, the conventional method, popularized by [Baron and Kenny \(1986\)](#), relies on the comparison of coefficients on treatment (here, the *hukou* reform) from two regressions: the first regression regresses the outcome on the treatment, and the second regression further includes the mechanism variable. The change in the treatment coefficient is interpreted as the treatment effect mediated by the proposed mechanism. The magnitude of the mediated treatment effect measures the importance of a mechanism. Although intuitive, this approach relies on strong assumptions (e.g., [Imai et al., 2011](#)). A researcher has to assume that: (i) conditional on the treatment, the mechanism variable is exogenous with respect to other unobserved determinants of the outcome; and (ii) the mechanism effect on the outcome is homogeneous. The first assumption is a key one: it ensures that the average mechanism effect can be identified. The second assumption allows the average mechanism effect estimated at the aggregate level to be applied at the individual level. Assumption (i) is often not plausible due to the existence of other post-treatment confounders related to the mechanism variable. In our method, we relax this assumption and employ an instrumental variable (IV) for the mechanism variable to identify the mechanism effect. We maintain assumption (ii) so that the IV-identified average mechanism effect in one population can be extrapolated to another population. By doing so, we preserve the simplicity of the conventional approach: the change in the treatment coefficient, when including the instrumented mechanism variable in a regression, can still be interpreted as the treatment effect mediated by a proposed mechanism. If the homogeneity assumption is relaxed, the IV-identified average mechanism effect (i.e., a local average effect, [Imbens and Angrist, 1994](#)) differs from the population average mechanism effect, and the change in the treatment coefficient is biased for the average mediation effect. We develop a simple test to assess the sensitivity of our conclusion to the homogeneity assumption and provide bounds for the average mediation effect.

When applying this method to our case, we use a shift-share IV that leverages variation in trade shocks in migrants' origins. This IV is strongly associated with outmigration from the destination. With this instrumentation, our results show that our measure of heightened settlement intentions (or equivalently, decreased outmigration rates) can account for 63 percent of the *hukou* reform's total effect on labor unrest. This result rests on the assumption that the mechanism effects are homogeneous. When relaxing this assumption and implementing our simple sensitivity test, we find that even in the most extreme case where the IV substantially overestimates the average mechanism effect, we can still conclude that heightened settlement intentions explain a nontrivial fraction (16 percent) of decreased labor unrest due to the *hukou* reform.

We present additional evidence that corroborates the importance of enhanced settlement intentions. We show that the *hukou* reform has a much more pronounced effect of reducing labor unrest in places where migrants come from nearby origins or have low cultural distance to the

natives—precisely where the reform should have the most salient effect of prompting migrants to stay because of reduced institutional barriers to integration. We also reject other alternative mechanisms through which the *hukou* reform may reduce labor unrest: (i) shifts in characteristics within migrants, (ii) immediate improvements in benefits available to migrants (e.g., labor market outcomes and family unification), and (iii) local governments’ tier social control.

In sum, we show evidence that the relaxation of integration restrictions—in our case, driven by China’s *hukou* reform—reduces social unrest due to migrants’ stronger settlement intentions that discourage participation. It is important to consider the generalizability of our findings. First, for settlement intentions to play a role, some authority (oftentimes, the state) should exert a strong influence over migrants’ welfare, thereby creating credible threats to deter participation in unrest when migrants intend to stay longer. This condition is met in China, where the state controls various resources crucial to livelihoods. We envision that this condition can hold broadly in autocracies. Even in democracies, there can be scope for migrants’ settlement intentions to matter. Immigrants’ rights, especially for undocumented immigrants, are heavily shaped by immigration law enforcement (e.g., deportation). For instance, Gonçalves et al. (2024) show that strict immigration enforcement in the US discourages immigrant victims from reporting offenses, even at the cost of victimization, indicating that government threats can effectively affect the behaviors of immigrants (who presumably would like to stay in the foreseeable future). Likewise, Alsan and Yang (2024) find that aggressive deportations of Hispanic noncitizens from the US generate fear among Hispanic citizen-headed households, and to protect noncitizen household members, these households reduce their participation in safety net programs. Second, in this paper, we focus on internal migrants. Compared to international migrants, they may be more responsive to reductions in institutional barriers to integration, as they face fewer cultural barriers to integration. In contrast, international migrants may experience a smaller increase in settlement intentions even when institutional barriers are lowered. However, some international migrants may have a smaller cultural distance from natives, and thus they can be similarly sensitive to reductions in institutional barriers to integration as internal migrants that we study in this paper. Consistent with this logic, even in our internal migration setting, we find that reducing institutional barriers has a more pronounced effect when migrants are culturally closer to natives and therefore are more inclined to stay if possible. Taken together, our findings are most applicable to the group of migrants who depend on the state for their livelihoods and whose integration is primarily restricted by institutional barriers.

Our paper engages with several strands of literature. First and foremost, it speaks to the relationship between migration policy and social stability. A noticeable body of literature in this domain focuses on the effect of international migration on crime (Spenkuch, 2014; Bianchi et al.,

2012; Bell et al., 2013; Nunziata, 2015; Ajzenman et al., 2023).⁶ This literature overall finds mixed effects. When significant effects do appear, they relate to financial crime and particular subgroups of immigrants with poor labor market opportunities. Nevertheless, immigration is viewed as a source of crime, fueling support for strict immigration enforcement (Nunziata, 2015; Ajzenman et al., 2023; Dinas and van Spanje, 2011). Our paper moves beyond migrant characteristics and highlights a distinct mechanism: lowering integration barriers extends migrants' expected length of stay, and in turn, it affects their sociopolitical behaviors. Longer horizons encourage migrants to take actions that facilitate their integration and bring benefits in the long run. This is in the spirit of a growing literature on how stay plans affect migrants' economic choices for assimilation (Dustmann and Görlach, 2016; Adda et al., 2022, 2025; Zaiour, 2023; Gathmann and Keller, 2018).

Second, our paper contributes to a small literature on China's *hukou* system. Exploiting variation from different episodes of *hukou* reforms, several papers have studied the *economic* consequences of migration barriers induced by the *hukou* system, including labor market outcomes, marriage market matching, and productivity (e.g., An et al., 2024; Han et al., 2015; Ngai et al., 2019). Scholars largely agree that the *hukou* system causes significant efficiency losses, and some have hinted that the system continues to exist due to political constraints.⁷ However, little attention has been paid to the *hukou* system's *political* implications. To the best of our knowledge, we are the first to examine the impact of a *hukou* reform on social stability. In this regard, we also contribute to the literature on political control, namely, the tactics used by the state to induce citizen compliance (for a review, see Hassan et al., 2022). One prominent example of nonviolent tactics is buying hearts and minds through government transfers and employment (e.g., Pan, 2020; Rosenfeld, 2021; Fish, 1905; Borjas, 1980; Kersting, 2023).

Last but not least, our paper adds to the econometric literature on causal mediation, which aims to formally estimate the average treatment effect mediated by a mechanism (Baron and Kenny, 1986; Imai et al., 2011; Pearl, 2009). As mentioned above, one key challenge is to identify the effect of the mechanism on the outcome. We overcome this challenge using an IV. We are not the first to use an IV for causal mediation. Imai et al. (2011) provide a framework with homogeneous effects and a single IV for the mechanism variable, and they show that comparing treatment coefficients in

⁶Two points should be noted when comparing our paper with this literature. First, we examine internal migration rather than international migration. However, as discussed above, the *hukou* system makes internal migration in China similarly restrictive to international migration elsewhere. Second, our measure of social stability is labor unrest. Unlike crime, which is inherently illegal, the labor unrest we study often involves workers' actions to claim their legal rights. Yet, the Chinese state's fears of labor unrest resemble other countries' concerns about crime. In both settings, migrants may weigh potential government responses when deciding whether to participate. With this in mind, insights from Chinese migrants' calculations of unrest can still be broadly informative.

⁷For instance, Au and Henderson (2006) argue that Chinese cities are undersized despite high urban agglomeration benefits; they claim that the *hukou* system is maintained in part due to "political pressure by urban residents who fear vast influxes of peasants." Vortherms (2023) provides interview evidence that Chinese officials view migrants as a source of crime and instability, and they take it into account when designing local *hukou* policies. Ngai et al. (2019) document that the *hukou* system distorts labor allocations and thus causes efficiency losses. We refer interested readers to other studies that underscore the *hukou* system's economic costs, such as Adamopoulos et al. (2024) and Gai et al. (2024) among others.

regressions with and without the mechanism variable identifies the mediation effect. Frölich and Huber (2017) present a framework of non-parametric identification under structural assumptions. Our method preserves the simple, regression-based approach in Imai et al. (2011) and proposes a sensitivity test to evaluate the robustness of conclusions about a mechanism’s importance in the presence of heterogeneous effects.

The remainder of this paper is organized as follows. Section 2 provides information on the institutional context. Section 3 describes our data and research design. Section 4 reports the effect of the *hukou* reform on labor unrest. Section 5 explores underlying mechanisms. Section 6 concludes. Additional results and discussions can be found in the [Online Appendices](#).

2 Institutional Context

In Section 2.1, we first briefly describe China’s *hukou* (household registration) system and how it obstructs free migration.⁸ We then provide key information on the 2014 *hukou* reform that we study in this paper. In Section 2.2, we present some background on labor unrest in China. Finally, in Section 2.3, we provide a conceptual discussion on how the *hukou* reform may affect labor unrest to fix ideas for our subsequent empirical investigation.

2.1 China’s *Hukou* System and Internal Migration

A Brief Overview. The *hukou* (household registration) system was instituted in 1958. Each Chinese citizen is assigned a *hukou* certificate at birth, which ties them to a specific location as their *official* residential location. People inherit their parents’ *hukou* locations. The registration location determines *where* a person is eligible for state transfers and public services. A person is only eligible in their registration location, regardless of the physical location. The geographic scope of eligibility varies by service, with the prefecture level—the administrative level between the county and the province—being the most consequential.⁹

There were two types of *hukou* certificates: agricultural and non-agricultural. Like the *hukou* location, the *hukou* type is passed on from parents to children. Rural residents were typically issued an agricultural *hukou*,¹⁰ which granted an allotment of land for cultivation to feed themselves and access to some social services provided by their registration locations. Urban residents were issued a non-agricultural *hukou* and were expected to work in factory or office jobs. Residents holding urban *hukou* could access locally funded social benefits, many of which were job-related

⁸We refer interested readers to Song (2014) and Chan (2019) for a more comprehensive account.

⁹An average prefecture had 4.2 million residents in 2010. Primary education is administered at the district or township level, while secondary education falls under county-level management. Social security programs, such as pensions, healthcare, and housing funds, are generally managed at the prefecture level, although in some regions these responsibilities are being shifted upward to the provincial level.

¹⁰One exception is government officials who worked in rural areas.

and included subsidized medical care, education for their children, and social assistance. Starting from the 1990s, some regions gradually removed the distinction in *hukou* types. This removal was eventually extended to the entire country in 2014, by the reform we study in this paper. Despite the removal of urban/rural *hukou* types, the key aspect of the *hukou* system remains unchanged: citizens can only access state transfers and public services in their registration locations.

The *Hukou* System as a Migration Barrier. Under Mao, the *hukou* system was created to restrict population mobility. People were expected to stay in their registration locations, which facilitated the government's urban-biased industrialization strategy that extracted resources from vast rural areas to subsidize urban areas. Transferring *hukou* registration across regions was restricted, especially from rural to urban areas, making permanent migration nearly impossible.¹¹ Even short-term trips required permits from the police; otherwise, the traveler would be expelled back to their *hukou* location (Cheng and Selden, 1994). During the Maoist era, most jobs were controlled by the state and food was rationed according to the *hukou* location; therefore, mobility restrictions could be strictly enforced.

In the post-Mao era, the *hukou* system was gradually relaxed, eventually allowing free movement across the country by the late 1990s. This led to massive migration flows within China, particularly from rural to urban areas (Facchini et al., 2019; Chan, 2018).¹² As of 2020, it is estimated that 286 million people in China were migrants, accounting for approximately 20 percent of the Chinese population (Guo et al., 2024). However, the *hukou* system remains in place under the management of local governments. Transferring the *hukou* registration is still restricted. Local governments have an incentive to limit transfers into their jurisdictions to avoid the fiscal burden of providing social services to migrants. They often only open transfers to migrants with substantial financial means, such as investors, home buyers, or highly educated professionals. Some local governments have even established a point-based system to evaluate migrants' qualifications and determine whether to grant *hukou* transfers (like Canada's Federal Skilled Worker program). Transfers through family members are not universally granted: newly married spouses may need to wait for years to be eligible for transfers, adult children are often ineligible for transfers along with their parents, and siblings and extended family members do not qualify for transfers at all. All in all, in modern-day China, transfers of *hukou* registration remain difficult, and the inability to transfer *hukou* constitutes a considerable cost of migration as migrants lose access to public services in migration destinations. Eli Friedman, a renowned scholar of labor politics in China, forcefully summarizes the reality in China as the "*urbanization of labor [rather than of people]*." That is, people are welcome to move to and work in cities, but they are not expected to permanently settle there (Friedman, 2022), and in fact, many migrants have no hope to eventually integrate into their migration destinations. Indeed, an average Chinese migrant only stays in the migration destination for 5–7 years (Meng, 2012).

¹¹Successful transfers were usually achieved by state employment, military service, and higher education.

¹²According to our calculations using the 2010 census, 72 percent of migrants, defined as individuals who lived in a prefecture different from the *hukou* prefecture for at least six months, are rural-to-urban migrants.

The 2014 *Hukou* Reform. On July 30, 2014, the Chinese central government initiated a nationwide reform of the *hukou* system (State Council, 2014a). Unlike previous local reform initiatives, this reform was centrally mandated. Critical to our research design, this reform has a population-based discontinuity rule for granting *hukou* transfers to urban areas, summarized in Table 1. Cities are categorized into five groups according to their urban population sizes: > 5 million, 3–5 million, 1–3 million, 0.5–1 million, and < 0.5 million.¹³ As a development strategy, the central government’s objective was to push the urbanization of medium- and small-sized cities while maintaining strict control over the expansion of large cities. Large cities (those with an urban population exceeding 3 million) are required to maintain tight control of *hukou* transfers using a points-based system that only incorporates select migrants, much like that seen in international migration settings.¹⁴ The migrants there face similar (or arguably more) barriers to transferring *hukou* after the reform. In contrast, the criteria for transferring *hukou* become much more lenient in medium and small cities (i.e., those with less than 3 million urban population) after the reform. These cities are set to accept a much broader base of migrants and offer a residence-based, accessible path to naturalization for migrants. Unlike previous high bars requiring substantial financial capacities (e.g., investment, home purchases, or high-tech employment), obtaining a local *hukou* now requires only a stable job, stable residence, and a minimum period of enrollment in the city’s social security system.¹⁵

In sum, after the reform in 2014, in cities with less than 3 million people, migrants face substantially fewer barriers to obtaining local *hukou* and eventually settling there. In this paper, we focus on the discontinuous variation in the criteria for granting local *hukou* around the 3-million population cutoff. The 3-million cutoff is arguably the most relevant one, as most of the very small cities already had easy *hukou* transfer policies (Song, 2014). In fact, the central government reiterated in 2016 and 2024 that cities with an urban population below 3 million must abolish *all* barriers to *hukou* transfers (State Council, 2016, 2024). In Section 4, we also empirically show that what matters is the 3-million cutoff, rather than other cutoffs specified in the reform.

2.2 Labor Unrest in China

Despite China’s autocratic regime, labor unrest is not uncommon in China. Several structural factors have contributed to this phenomenon. Notably, the literature on China’s labor politics highlights the role of institutional discrimination against migrant labor resulting from the *hukou* system (e.g., Lee, 2007; Chan, 2010; Friedman, 2014; Rho, 2023; Elfstrom, 2021; among others). Restricted social

¹³These cutoffs come from the Chinese government’s official categorization of city sizes (State Council, 2014b).

¹⁴For example, Shanghai assesses migrants across several dimensions, including age, educational attainment, technical skills, enrollment in local social security, potential contributions to local development, and any history of penalties (Shanghai Government, 2015).

¹⁵Having a stable job often means having an employment contract or being a business owner (with minimum requirements on tax payments and/or registered capital). Having a stable residence means either having a rental contract registered with the government or owning an apartment.

Table 1. Summary of the 2014 *Hukou* Reform

Urban population	Provisions on granting local <i>hukou</i>
> 5 million	Points-based systems must be established to select migrants.
3–5 million	Rules must be stricter than cities of the next tier. Cities are urged to establish points-based systems.
1–3 million	Local <i>hukou</i> is granted for migrants with a stable job, stable residence, and 1–5 years enrollment in basic social security.
0.5–1 million	Local <i>hukou</i> is granted for migrants with a stable job, stable residence, and 1–3 years enrollment in basic social security.
< 0.5 million	Local <i>hukou</i> is granted for migrants with a stable job and stable residence.

Note: This table summarizes the provisions of the 2014 *hukou* reform (State Council, 2014a). Having a stable job often means having an employment contract or being a business owner (with minimum requirements on tax payments and/or registered capital).

and economic mobility for migrants due to limited rights, combined with employers' rampant violations of basic statutory protections, fuels migrants' grievances and thus contributes to the occurrence of labor unrest, such as strikes, protests, and riots. More recently, legal reforms and labor shortages in labor-intensive sectors have shifted bargaining power in favor of migrant workers (Gallagher, 2017; Elfstrom and Kuruvilla, 2014). Despite a lack of official data on migrant labor's participation in labor unrest, many scholars have provided anecdotes from fieldwork suggesting that migrant workers indeed make up the majority of participants in labor unrest, especially those offensive actions that demand more interests other than defending minimum rights (Friedman, 2014; Rho, 2023; Goebel, 2019; Elfstrom, 2021).¹⁶ Corroborating this view, Figure A1 shows a positive relationship between labor unrest and the share of migrants in a region.

The Chinese state has been increasingly vigilant about labor unrest, especially in the last decade (Franceschini and Nesossi, 2018; Rho, 2023). Lorentzen et al. (2013) argue that the central government strategically tolerates labor unrest in which workers voice demands for their rights and interests because such unrest can serve as a signal for the central government to identify discontented groups. With this information, the government can then allocate resources to address grievances and manage local officials accordingly. However, the acceptable space of unrest has been codified in informal rules with an implicit warning that whoever crosses the boundary of acceptable protests will be repressed. "Unacceptable" protests include mass collective actions that threaten social stability. For instance, Rho (2023) finds that police are more likely to intervene when workers protest outside the factory compound. The regime has strictly restricted and punished

¹⁶Friedman (2014, pp. 14) claims that "anecdotal evidence suggests that they [migrants] are the primary actors in contemporary insurgency." According to Rho (2023, pp. 8), migrant workers' labor disputes comprised nearly 70 percent of all labor disputes in Beijing in 2010. Goebel (2019) analyzes social unrest on social media and finds that migrant workers have engaged in the largest number of protests. Elfstrom (2021, pp. 42) contends that "in general, nonlocals are now both the most likely to mobilize against their bosses and the most likely to choose extra-institutional channels to do so." Reassuringly, he finds that local migrant density is positively associated with strike incidents but negatively associated with formal disputes through legal channels.

independent labor organizing and social mobilization across workplaces or regions (Chen and Gallagher, 2018). It is worth noting that unions in China are government agencies and do not truly represent labor; therefore, they do not mobilize protests (Friedman, 2014). Additionally, due to the cadre evaluation system's emphasis on stability maintenance (Edin, 2003), local officials deal with unrest seriously and employ various strategies to mitigate potential threats to stability (Campante et al., 2023; You et al., 2022; Mueller, 2025).

2.3 How the *Hukou* Reform May Affect Labor Unrest

For Chinese migrant workers, the *hukou* reform creates an opportunity for permanent settlement (i.e., obtaining local *hukou*) that can benefit migrants. Therefore, migrants are more likely to pursue settlement in their migration destination, and this pursuit may lead to a special “investment” in the form of reduced engagement in labor unrest. Migrants hoping for permanent settlement may fear participating in labor unrest for several reasons. First, the *hukou* reform does not immediately entitle migrants to local *hukou*. Instead, it makes settlement more attainable than before; thus, migrants have to consider whether their political actions would undermine their chance of settlement. Second, migrants depend on the government to acquire permanent settlement. It is well known that the government dislikes labor unrest and may aggressively retaliate against participants when it deems necessary. With this knowledge, migrants may be deterred from joining unrest activities. Indeed, previous studies find that migrant workers are concerned about their actions irritating the government (Chen and Gallagher, 2018). Lastly, participation in unrest may indirectly undermine a migrant worker’s prospect of permanent settlement. Settlement requires migrants to have stable jobs and housing (see Section 2.1). These conditions may not be easily satisfied if a migrant worker is not welcomed by employers and landlords because of their prior participation in labor unrest (and, perhaps much worse, punishment by the government).

Migrants’ increased settlement intentions in the wake of the *hukou* reform effectively function as a disincentive for engagement in unrest. Before the reform, this disincentive was weak. Institutional barriers to *hukou* transfers made migration temporary, and migrants have little to lose for their long-term settlement. As a result, they may have incentives to engage in politically risky unrest to secure short-term benefits (e.g., recovering unpaid wages).

In spirit, the way that the *hukou* reform discourages unrest engagement is similar to the role of (intended) migration duration in shaping migrants’ *economic* choices, especially those concerning settlement and assimilation into the destination, because of high anticipated returns. This has been widely documented in existing literature. For example, Adda et al. (2022) leverage a panel dataset on immigrants and a dynamic model to highlight migrants’ return/stay plans as an important source of heterogeneity in their skill acquisition and career paths. Zaiour (2023) argues that violence at home raises Mexican immigrants’ intentions to stay in the US and thereby increases their propensity for naturalization and marriage to US citizens. Gathmann and Keller (2018)

exploit Germany's 1990 citizenship policy reform, and they find that faster access to citizenship increases migrants' investments in host country-specific skills, such as language proficiency and vocational training. In a recent paper, Adda et al. (2025) find that access to legal status decreases the probability of immigrants marrying natives and the divorce rates among native-immigrant couples. In Appendix C, we also present a simple model to formalize our argument.

Besides settlement intentions, the *hukou* reform may affect labor unrest through other channels. For instance, the reform may improve migrant workers' wellbeing, which reduces their grievances and thus reduces labor unrest. Reform cities may attract more population and/or change the composition of the population, which generates differential dynamics of unrest. The population growth may also lead to local governments' strategic responses to control society. Throughout the paper, we carefully examine these possibilities.

3 Data and Research Design

3.1 Sample Construction and Key Variables

Unit of Analysis. In this study, the unit of analysis is the prefecture. Prefectures, sometimes referred to as prefectural cities or simply cities, represent the administrative level between provinces and counties. In total, there are 333 prefectures in China.¹⁷ We also consider 4 provincial-level municipalities: Beijing, Tianjin, Shanghai, and Chongqing. For brevity, we also refer to these municipalities as prefectures in this paper. When constructing the sample, we exclude prefectures in Tibet and Xinjiang due to their distinct political environments. Our final sample consists of 287 prefectures for which data on urban population are available, allowing us to define each prefecture's reform status (discussed next).¹⁸ According to the 2010 population census, these prefectures account for 94.4 percent of the total population and 95.8 percent of the urban population in China.

Reform Status. As discussed in Section 2, prefectures with urban populations below 3 million should reduce barriers to *hukou* transfers. Thus, to define each prefecture's reform status, it is crucial to consider how the Chinese government counts the population. According to National Bureau of Statistics (2008), a prefecture's urban population consists of all residents who have lived in the

¹⁷This is based on the 2010 delineation; there are no significant changes to the delineation of prefectures over our sample period.

¹⁸Excluding prefectures without available urban population data removes 39 prefectures. Excluding Tibet and Xinjiang accounts for an additional 11 prefectures. In Appendix G.1, we show that our results are not driven by these exclusions.

prefecture's core urban district for more than six months.¹⁹ This includes both natives and migrants, regardless of *hukou* registration status. For the purposes of this paper, we use population data from the Urban Construction Statistical Yearbook (UCSY) published by the Ministry of Housing and Urban-Rural Development, which follows the same definition of urban population as in National Bureau of Statistics (2008).²⁰ The population estimates are derived from residential registration data maintained by prefectural police departments. To define a prefecture's reform status, we use the urban population in 2014, denoted by P_i , which was measured in the year when the reform took place. The binary treatment variable, $Reform_i = \mathbb{1}\{P_{i,2014} \leq 3 \text{ million}\}$, equals one if prefecture i 's 2014 urban population is below 3 million, and equals zero otherwise. Under this definition, 37 prefectures in the sample are classified as non-reform prefectures, while the remaining 250 are classified as reform prefectures.

Two points are worth noting regarding the definition of reform status. First, we verify the accuracy of the population-based reform status in capturing policy changes. To do this, we conduct a thorough review of *hukou* policy documents issued by provincial and prefectural governments.²¹ Based on our reading, we manually code up each prefecture's reform status, with the details of our coding process outlined in Appendix D. We then compare the manually coded reform status with the population-based reform status. The population-based definition proves to be highly accurate. Out of 287 prefectures in the sample, there are only 17 discrepancies ($17/287 = 6\%$) between the manually coded and population-based reform statuses.²² Therefore, in the subsequent analysis, we rely on the population-based reform status. However, to alleviate concerns about the discrepancies in reform status, we show the robustness of our results to excluding the 17 prefectures with discrepancies (see Section 4.3). Second, our definition is based on the urban population in 2014. One may wonder whether prefectural governments adjust their migration policies as the urban

¹⁹A prefecture's core urban district is a formal administrative district where the prefectural government is located. In addition to the core urban district, a prefecture may have other urban districts, such as the county seats of subordinate counties (World Bank, 2012). Since county seats are separate urban centers, their residents are not counted as part of the prefecture's urban population. Both the core district and county seats are considered cities and can be affected by reform. However, because the core district's population is much larger than that of county seats, it is the size of the core urban district that determines a prefecture's reform status. This can be seen from prefectural governments' guidelines for implementing the 2014 reform: they removed all restrictions in county seats while maintaining restrictions and/or removing some restrictions in core districts. For instance, Shijiazhuang prefecture of Hebei province specified (Shijiazhuang Government, 2015): "Lift household registration restrictions in county (city) urban areas and established towns... Relax the conditions for settling in the core urban district. If any of the following conditions are met in the urban district, the applicant and their co-residing spouse, children, and both spouses' parents may apply for local permanent household registration..."

²⁰The UCSY reports the urban native and urban migrant populations separately. We aggregate the two groups to calculate the total urban population.

²¹We collect these documents from government websites and news reports, as well as a database on *hukou* reforms built by Zhang and Lu (2019). Appendix D offers an example of these documents.

²²Table D2 in Appendix D tabulates the discrepancies. Eight small prefectures (urban population < 3 million) opted to maintain restrictions, whereas nine large prefectures (urban population > 3 million) opted to relax migration barriers. We discuss possible reasons for these discrepancies. Some small prefectures may have opted to maintain barriers because of their political importance or anticipated population growth. For instance, the Hebei provincial government explicitly required Langfang prefecture to maintain restrictions because the prefecture is adjacent to Beijing, meaning that it houses many of Beijing's migrant workers. The Guangdong provincial government required two prefectures in the Pearl River Delta, Zhuhai and Zhongshan, to maintain restrictions, likely because of recent population growth. However, it is less clear why those nine large prefectures opted to relax restrictions.

population moves above or below the 3 million threshold. To the best of our knowledge, this is not the case. According to our review of local governments' documents regarding the *hukou* reform, by 2015, most prefectures had guidelines for implementing the central government's directive, and we do not observe amendments in subsequent years.

Labor Unrest. Our data on labor unrest are from the China Labor Bulletin (CLB), a non-profit organization based in Hong Kong that has monitored incidents of worker collective actions across China since 2011.²³ Our sample consists of collective actions from 2011 to 2019. The sample ends just before the outbreak of COVID-19. Due to the lack of administrative data on labor unrest in China, this dataset has been frequently cited by news media outside China (e.g., Hernández, 2016) and used in research on social unrest in China (e.g., Campante et al., 2023; Qin et al., 2024).

The CLB's coders collect information on unrest events primarily from China's domestic social media platforms: Weibo, WeChat, Douyin, Kuaishou, and others. The coders verify the accuracy of collected information and record only those events that have complete information on the location, date, cause(s), industry, and relevant company. The CLB data report 11,733 labor collective action events between 2011 and 2019.²⁴ Given how the CLB dataset is collected, events in the dataset should be considered as representing severe labor conflicts, where workers take to the streets and demand public attention. For 83 percent of the events in the dataset, workers conduct demonstrations in public spaces in the form of protests, marches, sit-ins, traffic obstruction, and even suicide threats. Recall from Section 2.2 that migrant workers are the major participants in labor unrest and especially in these demonstrative actions. The CLB often records multiple causes of an unrest event, but the most common reason is wage arrears, which account for 72 percent of all protest events. Job displacement accounts for 11 percent, and demands for welfare benefits are cited in 7 percent of events.

A natural question is to what degree CLB data reflect underlying patterns of labor conflict in China. We show that the events in the CLB data exhibit similar trends to those seen in other data sources of labor conflict. We draw a comparison to the Global Database of Events, Language, and Tone (GDELT), a commonly used dataset on social unrest at the global level (see a review by Cantoni et al., 2023). The GDELT Project has conducted automated scraping of the world's news media since 1979. In the GDELT data, we define any event as a labor unrest event if it falls in the "Protest" category and has labor recorded as one of the involved parties. Because the CLB specifically focuses on labor unrest and has human coders carrying out data collection and cleaning, it includes many more labor unrest events than the GDELT: the CLB identifies 11,733 events, whereas GDELT identifies only 4,681 events. Nonetheless, both datasets display quite similar national trends in labor unrest (see Figure A2).²⁵ Between 2011 and 2019, labor unrest in China was on the rise. CLB recorded 135 events in 2011, and the number surged to 2,719 in 2015

²³CLB website: <https://clb.org.hk/en>. CLB was shut down on June 12, 2025 (Leung, 2025).

²⁴The vast majority (11,451 events) occurred in the 287 prefectures included in our main sample.

²⁵GDELT is not suitable for a regression analysis at the subnational level. GDELT only geocodes 1,112 labor unrest events at the prefecture level, while the remainder are recorded using either the centroid of China or a province.

and 2,629 in 2016, partly due to China's sluggish export growth (Campante et al., 2023). Although the incidence of labor unrest declined after 2015, it remained high, averaging 1,430 events per year between 2016 and 2019.

Auxiliary Data. We use multiple auxiliary datasets to validate the research design and explore mechanisms. They include prefecture-level covariates collected from population censuses, migrant surveys, trade data, and biographical data on local officials, among others. Appendix E describes these data sources, and we introduce them when they become pertinent to the analysis.

3.2 Estimating the Causal Effect of the *Hukou* Reform on Labor Unrest

To estimate the causal effect of the *hukou* reform, an intuitive strategy is a difference-in-differences (DiD) design, which compares the trajectories of unrest between reform and non-reform prefectures. It can be implemented by the following two-way fixed effects (TWFE) model:

$$\frac{Unrest_{it}}{L_{i,2010}} = \beta (Reform_i \times Post_t) + \lambda_i + \mu_t + \varepsilon_{it}. \quad (1)$$

The dependent variable, $\frac{Unrest_{it}}{L_{i,2010}}$, represents the unrest rate, measured as the number of unrest events per million prime-age population (aged 25–54 years old). $Reform_i$ is an indicator for prefecture i 's reform status, taking value one if prefecture i 's urban population in 2014 is below 3 million. $Post_t$ is an indicator that equals one for years from 2014 (the first year the reform went into effect) onward. We include prefecture and year fixed effects, denoted λ_i and μ_t , respectively. The error term, ε_{it} , is clustered at the prefecture level.

The ordinary least squares (OLS) estimand, β , identifies an average causal effect of the *hukou* reform on labor unrest, if a parallel trends assumption is met: reform and non-reform prefectures, on average, should have similar trends in unrest in the absence of the reform. However, this assumption is questionable in our setting as it requires more populous regions to be on parallel trends in labor unrest with less populous regions. This assumption may be violated because the urban population itself, which determines the reform status, can be associated with differential patterns in unrest for several possibilities. For example, Acemoglu et al. (2020) document a positive causal relationship between population and conflict due to competition for scarce resources. It may be easier to organize unrest in more populous regions (Wallace, 2014). The local governments of more populous regions may also differ in their capacity to handle unrest threats.

To address this concern, we modify Equation 1 and explicitly include flexible controls for the urban population. The regression model is specified as follows:

$$\frac{Unrest_{it}}{L_{i,2010}} = \beta (Reform_i \times Post_t) + \lambda_i + \mu_t + f(\tilde{p}_i; \zeta_{Reform,t}) + \varepsilon_{it}. \quad (2)$$

The newly included variable, $\tilde{p}_i = \log(3) - \log(P_{i,2014})$, is the centered log urban population; it captures the deviation of prefecture i 's log urban population from $\log(3)$, the cutoff deciding reform status.²⁶ f is a polynomial function of \tilde{p}_i , and $\zeta_{Reform,t}$ is a vector of coefficients on \tilde{p}_i in the polynomial function. Importantly, as the subscripts indicate, coefficients in $\zeta_{Reform,t}$ are allowed to vary over time and by reform status.

This design is a marriage of difference-in-differences (DiD) and regression discontinuity (RD) designs, creating a difference-in-discontinuity (DiDC) design where \tilde{p}_i is the running variable.²⁷ It exploits the discontinuous variation in reform status around \tilde{p}_i . In the spirit of the classical RD design, β identifies the average causal effect of the *hukou* reform on labor unrest at $\tilde{p}_i = 0$. The causal interpretation hinges on the smoothness assumption that, in the absence of the *hukou* reform, the trends in labor unrest would have varied smoothly around $\tilde{p}_i = 0$. In essence, this is a local version of the parallel trends assumption, which is weaker than the global version underlying Equation 1 that requires similar trends between average reform and non-reform prefectures. In Section 4.1, we discuss the validity of our research design.

To gauge the dynamics of reform effects and shed light on the validity of our research design, we also estimate an event-study specification:

$$\frac{Unrest_{it}}{L_{i,2010}} = \sum_{\tau \neq 2013} \beta_\tau (Reform_i \times \mathbb{1}\{\tau = 2014\}) + \lambda_i + \mu_t + f(\tilde{p}_i; \zeta_{Reform,t}) + \varepsilon_{it}. \quad (3)$$

The pre-reform year 2013 is the reference year. β_τ 's ($\tau \geq 2014$) capture the dynamic reform effects. The pre-reform coefficients β_{2011} and β_{2012} constitute a pretrend test as in DiD designs: we would expect them to be small if the smoothness assumption holds.

To estimate Equations 2 and 3, we follow Gelman and Imbens (2019) and let f be a first-order polynomial function. In most of our analysis, we estimate results using the full sample of prefectures. Because the number of reform prefectures far exceeds that of non-reform prefectures (250 versus 37), restricting our sample to a narrow bandwidth around $\tilde{p}_i = 0$ would exclude a large portion of non-reform prefectures and thus limit statistical power. We place equal weights on prefectures (i.e., we use the uniform kernel). In Section 4, we show that our results are robust to different empirical decisions, including choices of alternative polynomial orders, bandwidths, and kernels.

²⁶We consider the deviation in logs because the distribution of urban population $P_{i,2014}$ is very skewed (see Figure A6). In Table B1, we show that using the deviation in levels, $3 - P_{i,2014}$, to construct polynomials produces similar results.

²⁷Compared to the RD design, one strength of the DiDC design is that it can improve the precision of estimates because it exploits the panel structure to control for time-invariant unobservables. However, the results are similar if we implement an RD design for each period (see Figure A3).

4 Main Results

This section presents the main results of our paper. We start by discussing the validity of our research design in Section 4.1. Section 4.2 then reports the estimated effects of the *hukou* reform on labor unrest using the DiDC design. Section 4.3 presents a battery of robustness checks.

4.1 Validity of the Research Design

Recall that our research design leverages variation in labor unrest trends across the cutoff of 3 million urban population, controlling for trends in the urban population. Thus, the identification assumption is that there is no discontinuous change in labor unrest trends around the reform cutoff in the absence of the *hukou* reform. In the following, we discuss a set of potential threats to this smoothness assumption, and we address them using tools from the RD literature (e.g., the McCrary test and balance tests) as well as tests specific to the Chinese context.

4.1.1 Concern 1: Manipulation of Population Statistics to Select Reform Status

The smoothness assumption is violated if the agents (in our case, the prefectural governments) precisely manipulate urban population statistics to sort into certain reform status (Lee and Lemieux, 2010). In principle, manipulation is not infeasible in our case, as prefectural officials can influence the reported population statistics to justify their preferred reform status. We present a set of evidence that rules out the presence of manipulation.

First, it is impractical to substantially manipulate urban population statistics for specific reform status because the new urban population cannot change too greatly from the historical level. In fact, from 2013 to 2014, only one prefecture's urban population grew from below 3 million to above 3 million, and zero prefectures had urban population fall from above 3 million to below 3 million. This indicates that manipulating population statistics to select reform status is not prevalent.

Second, if there is systematic manipulation of urban population to select certain reform status due to potential benefits, we would expect a significant bunching near the cutoff of 3 million (or equivalently, $\tilde{p}_i = 0$). However, we do not detect this phenomenon. Figure 1 presents the density of the running variable $\tilde{p}_i = 0$. The McCrary (2008) test confirms the smoothness of the density function around $\tilde{p}_i = 0$, suggesting a lack of manipulation. In Figure A7, we also examine the density of the running variable defined using the 2015 urban population, and we again do not detect a discontinuity in the density. Therefore, it is not the case that prefectural governments manipulated urban population statistics *ex post* to make reform choices appear to be more legitimate.

Lastly, for manipulation to occur in practice, there must be some benefits for local officials to do so. In the Chinese context, such benefits are predominantly bureaucratic promotion. A large body

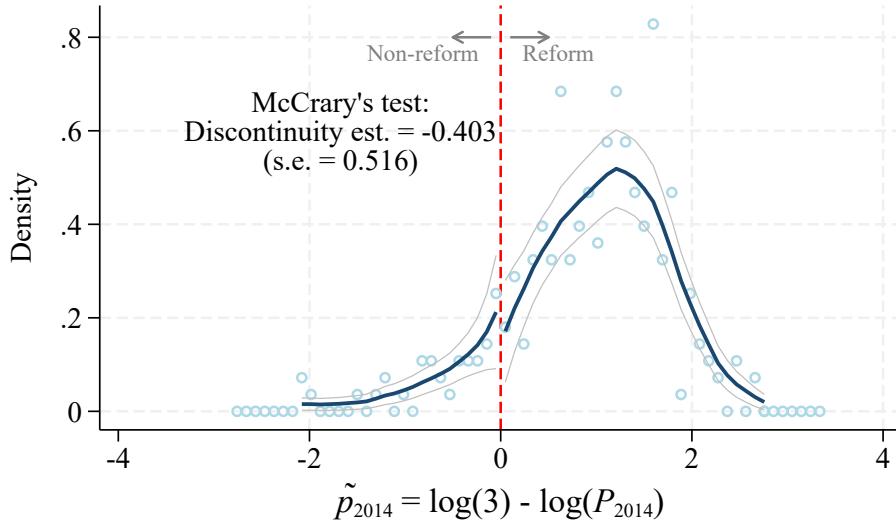

Figure 1. Density of Centered Log Urban Population of 2014

Note: This figure depicts the density of centered log urban population of 2014, $\tilde{p}_{i,2014}$. We report the McCrary's test of density discontinuity at $\tilde{p}_{i,2014} = 0$.

of literature has documented that promotion incentives play a central role in determining Chinese bureaucrats' choices and policy-making (e.g., Wang et al., 2020; He et al., 2020; Jia, 2024). Zeng and Zhou (2024) find that promotion-motivated local officials may manipulate GDP statistics to deliver better observed performance. However, unlike the manipulation of GDP statistics, there is no strong argument that the upper-level government should evaluate local officials directly based on the reported (changes to) urban population. One indirect but overly sophisticated argument is that local officials may want to *dodge* the *hukou* reform to avoid social instability threats brought by increased population inflows. This may improve the official's chance of promotion, given that stability maintenance has been widely seen as necessary for career advancement (Edin, 2003). One immediate implication of this argument is that officials with stronger promotion incentives may *over-report* urban population growth. However, we find little support for this hypothesis. Following Wang et al. (2020), we estimate an index for *ex-ante* promotion prospects (see Appendix E for estimation details). We find this index has no discernible association with observed growth in urban population between 2013 and 2014 (see Table B2). If anything, the association has a negative sign, the opposite of what a promotion-motivated manipulation story would predict.

4.1.2 Concern 2: Heterogeneity Between Prefectures

Our identification assumption requires that, without the *hukou* reform, *trends* in the determinants of labor unrest are similar between prefectures near the 3 million cutoff. This assumption is untestable because we do not observe the outcomes in the absence of the reform. Nonetheless, we can assess the plausibility of the identification assumption by examining the *pretrends*. Specifically, we run the

following RD regression:

$$\Delta W_{it} = \alpha_0 + \alpha_1 Reform_i + f(\tilde{p}_i; \zeta_{Reform,t}) + \mu_t + \nu_{it}, \quad t \leq 2013. \quad (4)$$

Here, $\Delta W_{it} = W_{it} - W_{i,t-1}$ is the change in a covariate. Our sample includes two pre-reform episodes: 2011–2012 and 2012–2013. Equation 4 stacks these two episodes with the year fixed effect μ_t . Panel A of Table 2 reports the results. We begin by estimating Equation 4 without including the polynomial function $f(\tilde{p}_i; \zeta_{Reform,t})$; thus, α_1 captures the average difference in pretrends between reform and non-reform prefectures. Columns (1) and (2) report the estimated α_1 and the standard error. We find that, on average, reform prefectures have lower growth in unrest rates compared to their non-reform counterparts. We also find that reform prefectures have differential pretrends in other dimensions. They exhibit lower population growth and, interestingly, higher GDP growth; however, there are no discernible differential trends in local governments' fiscal expenditures as well as "carrot and stick," as measured by expenditures on social security and public security (police). These patterns suggest that a simple DiD design may not be able to reliably estimate the causal effect of the *hukou* reform on labor unrest.

We next estimate Equation 4, controlling for polynomials $f(\tilde{p}_i; \zeta_{Reform,t})$. As in RD designs, α_1 captures pre-trend differences at $\tilde{p}_i = 0$. Columns (3) and (4) in Panel A of Table 2 report the estimated α_1 and its standard error. By comparing prefectures barely eligible for the reform with those barely ineligible, controlling for the polynomial substantially shrinks the pretrends differences found in Columns (1) and (2) and eliminates all three statistically significant differences. Importantly, there are no longer differential trends in labor unrest. The lack of differential pretrends is also evident in the RD plots displayed in Figure A8A.

The checks for pretrends lend support to our research design. We also examine predetermined characteristics that may be associated with the evolution of labor unrest. Specifically, we estimate a cross-sectional variant of Equation 4 where the dependent variable is a characteristic in the base year (2010, the most recent year prior to our sample period for which a population census is available). Inspired by existing research on unrest, we examine a set of population-level variables associated with unrest occurrences, including the share of males, the share of migrants, the shares of construction/manufacturing/transportation workers, as well as the share of internet users. Panel B of Table 2 presents the results. As above, Columns (1) and (2) report estimates from the specification without including polynomials, and Columns (3) and (4) report estimates after adding polynomials to the regressions. The inclusion of polynomials substantially shrinks the differences in predetermined characteristics, although the share of migrants slightly differs between reform and non-reform prefectures at the 10 percent significance level. Figure A8B visualizes the RD regressions reported in Columns (3) and (4), confirming the balances in predetermined characteristics. In Section 4.3, we also show that our results are robust to a variety of strategies to control for potential covariate-related differential trends.

In sum, the results support the identification assumption of our research design: absent the *hukou* reform, the underlying trends in labor unrest would have evolved smoothly around the reform cutoff.

Table 2. Examining Smoothness in Covariates

Dependent	(1) Coef. on <i>Reform</i>	(2) SE	(3) Coef. on <i>Reform</i>	(4) SE
Panel A: Pretrends (2011-2012, 2012-2013)				
ΔUnrest/L	-0.352** (0.161)		0.070 (0.158)	
ΔLog population	-0.019*** (0.003)		-0.005 (0.005)	
ΔLog GDP	0.009* (0.005)		0.001 (0.008)	
ΔLog expenditure	0.009 (0.007)		0.001 (0.009)	
ΔLog expenditure on social security	0.018 (0.013)		0.014 (0.021)	
ΔLog expenditure on public security	0.012 (0.007)		-0.005 (0.011)	
Year FE	Yes		Yes	
Polynomials			Yes	
Panel B: Predetermined characteristics (2010)				
Share of males	-0.001 (0.002)		-0.003 (0.003)	
Share of migrants	-0.166*** (0.031)		-0.067* (0.036)	
Share of construction workers	-0.006 (0.004)		0.008 (0.006)	
Share of manufacturing workers	-0.140*** (0.029)		-0.054 (0.042)	
Share of transportation workers	-0.016*** (0.003)		-0.008 (0.005)	
Share of internet users	-0.165*** (0.061)		0.044 (0.086)	
Polynomials			Yes	

Note: This table examines the smoothness in covariates. Panel A looks at pretrends for 2011–2012 and 2012–2013. Panel B looks at predetermined prefectural characteristics measured in 2010. Columns (1) and (2) report the regression of the dependent on the reform indicator $Reform_i$ (controlling for year fixed effects for Panel A). Columns (3) and (4) report estimation results for the regression that additionally controls for the linear polynomial of $\tilde{p}_{i,2014}$ that is allowed to vary on each side of the reform cutoff. Standard errors clustered at the prefecture level are reported for Panel A, and heteroskedasticity-robust standard errors are reported for Panel B.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

4.1.3 Concern 3: Other Policies Correlated with Urban Population

Another concern is that if the urban population also determines policies other than the *hukou* reform and those policies can also influence labor unrest, our estimates may conflate the effects of multiple policies. This makes it difficult to isolate the specific effect of the *hukou* reform.

For policies that existed prior to the *hukou* reform, prefecture fixed effects should control for their influence, provided that their effects are time invariant. We can further evaluate the performance of prefecture fixed effects by examining pretrends. As Table 2 shows, when applying our research

design, there are no significant pretrends in labor unrest and other potentially unrest-conducive variables leading up to the *hukou* reform, suggesting that our results are unlikely to be driven by preexisting policies correlated with urban population.

More concerning are policies with provisions that vary by urban population and were enacted simultaneously with the *hukou* reform. If such policies also influence labor unrest, it would be impossible to disentangle the effects of the *hukou* reform from those of other policies. To alleviate this concern, we conduct an extensive review of policies related to urban population. Appendix F provides more details of this exercise. We use the *PKULaw* database—a large database of Chinese laws maintained by Peking University and frequently used in research on policy-making in China (Wang and Yang, 2025; Tian, 2024)—to identify policies that mention “urban population” or other similar terms.

Our reading suggests that these policies are unlikely to contaminate our estimates of the effects of the *hukou* reform on labor unrest. We find that most policies only reference “urban population” as part of a description, rather than specifying provisions that vary by urban population. For example, the central government approval of a prefecture’s urban planning may include a projection of urban population. A small number of policies do include provisions based on population tiers, but these focus on domains unrelated to labor unrest, such as prefabricated construction, public transit systems, and domestic services. Additionally, in Section 4.2, we conduct placebo tests estimating “effects” at cutoffs other than 3 million. We find null effects, indicating that our estimates are not confounded by other policies correlated with the urban population.

4.1.4 Concern 4: Anticipation of the Reform

One potential concern is that people may have anticipated the reform and altered their behavior preemptively, or that local governments, with insider information, may have adjusted policies in preparation for the upcoming change in the migration regime. If so, there may be differential dynamics in labor unrest between reform and non-reform prefectures, which can threaten the validity of our research design. However, our previous results suggest that this concern about anticipation is unfounded. In Table 2, we find no differences in the pretrends of labor unrest, population growth, GDP growth, and local governments’ fiscal expenditures. Furthermore, we use online searches to examine the existence of anticipation. Figure A9 presents searches for *hukou*- and *hukou*-reform related terms on Baidu, Google’s Chinese counterpart. We see transitory spikes in searches for these terms after July 30, 2014, the date when the *hukou* reform was publicly announced. There were no preexisting trends in searches before the announcement of the reform, and the search spikes quickly dissipated. These patterns indicate the absence of anticipation of the reform.

4.2 The Effect of the *Hukou* Reform on Labor Unrest

4.2.1 Main Findings

We begin by examining the dynamics of labor unrest in 287 prefectures from 2011 to 2019. Figure 2 presents the event-study estimates for our difference-in-discontinuity (DiDC) design based on Equation 3. Comparing prefectures around the reform cutoff, we observe no differential trends in unrest leading up to the central government's reform initiative. After the reform went into effect, reform prefectures experienced a decline in unrest rates relative to non-reform prefectures. The divergence in labor unrest trends peaked in 2015 and stabilized thereafter.²⁸

We conduct several checks for this trend break. First, in Figure A10, we find similar patterns when we control for province-specific linear trends. Second, using additional data on labor unrest from Elfstrom (2017), we can extend the pretrends in the event-study estimation back to 2003. Reassuringly, Figure A11 shows a lack of pretrends. Lastly, to further evaluate the significance of the trend break, we implement a sensitivity test developed by Rambachan and Roth (2023), with results reported in Appendix G.2. The test extrapolates the differential trends indicated by estimated pretrends to the post-reform period and examines, conditional on the extrapolated trends, whether the post-reform effects are still statistically significant. The results imply that one can conclude that the *hukou* reform significantly reduced labor unrest, unless there exist extremely nonlinear differential trends.

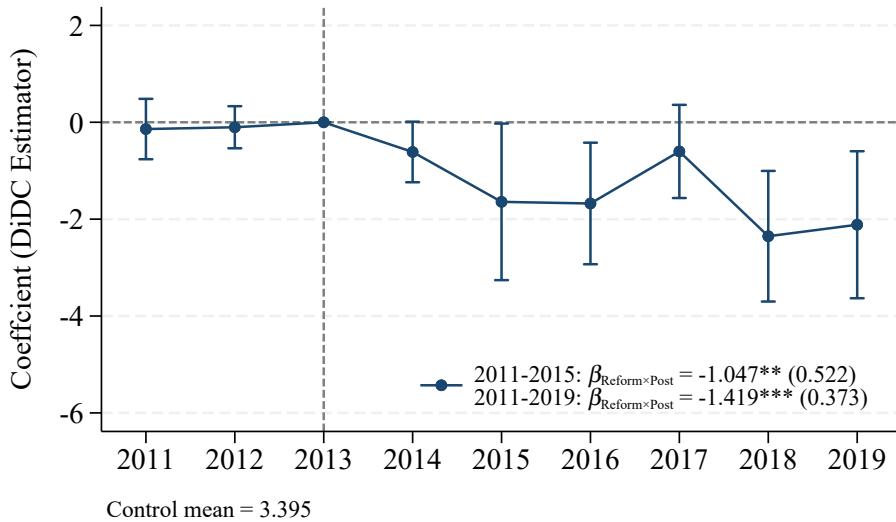

Figure 2. Dynamic Effects of the *Hukou* Reform on Labor Unrest

Note: This figure presents the dynamics of labor unrest from estimating Equation 3. The solid dots are point estimates, and the caps are the 95 percent confidence intervals. Standard errors clustered at the prefecture level are used for constructing the confidence intervals.

²⁸For completeness, Figure A4 compares the DiD and DiDC estimates. The DiD estimates exhibit significant downward pretrends, as shown in Table 2, but the post-trends are similar to what the DiDC estimates display.

We then estimate Equation 2 to summarize the dynamic effects. Table 3 reports the estimates. As the small number of non-reform prefectures may limit the validity of asymptotic testing, we also report p -values calculated from permutation tests. Column (1) shows that from 2011–2015, the *hukou* reform reduced annual labor unrest by 1.047 events per million prime-age population relative to non-reform prefectures, and Column (2) implies that for the entire period covered by our sample, 2011–2019, the point estimate implies that reform prefectures experienced 1.419 fewer annual unrest incidents per million prime-age population relative to non-reform prefectures. Inference based on clustered standard errors and permutation tests confirms that the estimates are statistically distinguishable from zero.

Consider the estimate for the period between 2011–2019. The magnitude of the estimate amounts to about 42 percent ($= 1.419/3.395$) of the mean of non-reform prefectures.²⁹ We also compare the estimated effect of the *hukou* reform to the causal effect of negative economic shocks. [Campante et al. \(2023\)](#) find that China’s export slowdown during 2013–2015 increased labor unrest. We replicate their estimation using only the reform prefectures to hold constant the impacts of the *hukou* reform, and we find that a per \$1,000 decrease in per-worker exports causes 0.397 more labor unrest events per million workers.³⁰ Therefore, the estimated effect of the *hukou* reform amounts to a \$3,576 increase in per-worker exports; put this number in perspective, it is about one standard deviation of per-worker exports across Chinese prefectures during 2013–2015. CLB also reports coarse information on the scale of each unrest event: small scale (1–100 participants), middle scale (101–1,000 participants), or large scale (1,001–10,000 participants). Exploiting this information to categorize unrest events, we find that the *hukou* reform mainly reduced small- and middle-scale labor unrest events, but not large-scale unrest events (see Table B3 and Figure A5). Taking those estimates for a back-of-the-envelope calculation, the *hukou* reform reduced the share of protesting workers in the labor force by 0.003–0.041 percent.

In Appendix G.3, we show that our results are robust to alternative empirical decisions, including choice of bandwidth, kernel, and polynomial order. Point estimates remain stable when varying bandwidths, albeit with large standard errors when restricting to small bandwidths. We also continue to see a strong effect of the *hukou* reform on decreasing labor unrest rates when using different kernels and orders of polynomials.

²⁹We note that the 95 percent confidence intervals include a wide range of values. One can have 95 percent confidence that the *hukou* reform decreased the labor unrest rate by 0.685 to 2.153 incidents per million prime-age population, which amounts to 20–63 percent of the average labor unrest rate in non-reform prefectures.

³⁰[Campante et al. \(2023\)](#) use a Bartik IV strategy. In their main specification, they use an unbalanced panel of 278 prefectures from 2013–2015 and estimate that a per \$1,000 decrease in per-worker exports causes 0.173 (SE = 0.075, N = 822) events per million workers in labor unrest. Restricting to 243 reform prefectures, we estimate an effect of 0.397 (SE = 0.195, N = 718).

Table 3. The Effect of the *Hukou* Reform on Labor Unrest

	(1)	(2)
	Unrest/L 2011–2015	Unrest/L 2011–2019
Reform × Post	-1.047** (0.522)	-1.419*** (0.373)
Control mean	2.501	3.395
Permutation test <i>p</i> -value	0.000	0.000
Prefecture FE	Yes	Yes
Year FE	Yes	Yes
Polynomials	Yes	Yes
Observations	1,435	2,583
<i>R</i> ²	0.700	0.601

Note: This table presents the results for the effect of *hukou* reform on labor unrest rates. Columns (1) and (2) use the full sample. Columns (3) and (4) use the narrow sample that uses the optimal bandwidth proposed by [Imbens and Kalyanaraman \(2012\)](#). Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

4.2.2 Alternative Interpretations

We interpret our findings as evidence of the causal effect of the *hukou* reform in reducing labor unrest rates. We now present additional results to tease out statistical artifacts that may explain our findings.

Unobserved Determinants of Unrest. One competing interpretation of our findings is that they merely reflect unobserved determinants of labor unrest that correlate with urban population and have time-varying impacts. This may not be very likely given the lack of urban population-correlated policies and the balanced pretrends. Nevertheless, we investigate this possibility using a placebo test. Specifically, we implement our research design to estimate the “causal effect” of having urban population below a cutoff other than 3 million.³¹ Figure 3 reports the results of this exercise. We see that 3 million is the only point where there is a significant negative effect, whereas there is a null effect elsewhere. These results indicate that our findings are not likely driven by the impacts of other urban population-correlated factors. In addition, they imply that the outcome only changes discontinuously at the cutoff of 3 million, which strengthens the validity of our research design, which requires the smoothness of outcomes at points other than the cutoff of 3 million.

³¹For a given new cutoff c , the exercise is operationalized by redefining $Reform_i$ as $\mathbb{1}\{P_{i,2014} \leq c\}$ and \bar{p}_i as $\log(c) - \log(P_{i,2014})$ in Equation 2. To avoid contamination due to treatment effect at the true cutoff of 3 million, we follow [Cattaneo and Titunik \(2022\)](#) and only use the sample of prefectures with urban population below (above) 3 million when estimating the effect at a cutoff below (above) 3 million.

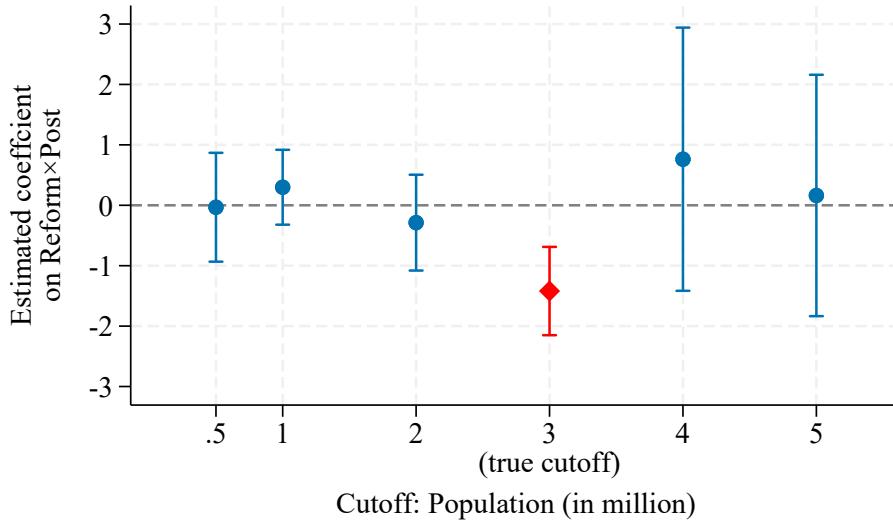

Figure 3. Estimates Using Falsified Cutoffs

Note: This figure presents the RD-DiD estimates from Equation 2 using falsified cutoffs: 0.5 million, 1 million, 2 million, 4 million, and 5 million. To avoid contamination due to real treatment effects at the 3 million cutoff, following [Cattaneo and Titunik \(2022\)](#), we use only prefectures below 3 million for 0.5 million, 1 million, and 3 million cutoffs, and only prefectures above 3 million for 4 million and 5 million cutoffs. The solid dots are point estimates, and the caps are 95 percent confidence intervals. Standard errors clustered at the prefecture level are used to construct confidence intervals.

Role of Labor NGOs. One may wonder if growing restrictions on labor NGOs in China can explain our results. Labor NGOs in China mainly assist labor by providing legal aid. However, some labor NGOs are movement-oriented. These movement-oriented NGOs are more active in Guangdong due to the province’s proximity to Hong Kong ([Li, 2021](#); [Fu, 2018](#)). To control for the role of labor NGOs, in Table B4, we use several strategies: (i) controlling for interactions between distance to Hong Kong and year fixed effects; (ii) dropping prefectures within 500km or 1,000km of Hong Kong; and (iii) dropping Guangdong province from the sample. Across these strategies, we find a stable negative effect of the *hukou* reform and labor unrest. This suggests that our results cannot be simply explained by variation in the influence of labor NGOs in China.

Differential Reporting of Local Events. Since our measure of the unrest rate from the CLB relies on online posts about labor unrest events, one may be concerned that our finding is an artifact of differential reporting of local events between reform and non-reform prefectures. This would be the case if reform prefectures report fewer events than non-reform prefectures after the reform went into effect. In Appendix G.4, we present several results addressing this concern.

First, we show that the *hukou* reform had no significant impacts on the number of general events or the number of protests reported in GDELT, a database that focuses on a wide range of topics including but not limited to labor unrest (see Columns (1) and (2) of Table G2). This suggests a lack of differential changes in the coverage of local events.

Second, we control for variation in labor unrest rates that is likely a result of China's internet censorship. Specifically, we use the measure of province-level censorship intensity from Qin et al. (2017)—the share of deleted posts on *Weibo* ("Chinese Twitter," China's largest social media platform)—as a proxy for the censorship apparatus' attention or efforts within a region. We control for interactions of this measure and year dummies in Equation 2. We find that the estimated effect on labor unrest of the *hukou* reform does not change markedly (see Column (3) of Table G2), suggesting that our findings can not be explained by differential trends in internet censorship.

Lastly, we address self-censorship as another source of differential reporting. If workers in reform prefectures are less likely to report their actions online than their counterparts in non-reform prefectures, then we would observe a mechanical decrease in labor unrest rates in reform prefectures. To examine the role of self-censorship, we consider the most influential scenario in which self-censorship would drive our results. If post-reform self-censorship rose primarily in reform prefectures that reported high pre-reform unrest rates, we would be more likely to obtain an artificial, negative effect of the *hukou* reform on labor unrest rates. If the dynamics of self-censorship play a major role in our findings, then excluding reform prefectures with high pre-reform unrest rates would attenuate the estimated effect of the *hukou* reform on labor unrest. However, as shown by Figure G6, the estimated effect remains stable when excluding reform prefectures with high pre-reform unrest rates, indicating a limited role of self-censorship in explaining our results.

Population Growth. We investigate if our results are due to mechanical changes in population growth and associated disproportional growth in labor unrest. Note that our results are against the common concern that lax migration laws may induce instability because they increase the population. In Appendix G.5, we find that the reform had no discernible effects on population growth. If anything, the population size gap between reform and non-reform prefectures grew over time. This echos recent evidence suggesting that Chinese migrants prefer to go to large cities because of the high wages there, and therefore a reform that makes migration to small cities less costly can hardly alter the pattern (Chen and Fu, 2023).³² Our baseline measure calculates the labor unrest rate using a fixed population size (prime-age population in 2010, see Equation 2). In Appendix G.6, we show that the results hold even if we account for the time-varying population size. Taken together, variation in population size cannot fully explain our findings.

A Natural Decline in Protests Against the *Hukou* Policy. One may argue that the observed decrease in labor unrest is mechanical, if most migrants had protested against the *hukou* policy, and the *hukou* reform would remove the need for protest by entitling migrants to local citizenship. We believe this interpretation is implausible in this context. First, in Appendix G.5, we find that the *hukou* reform had no significant impacts on native urban population (i.e., urban residents with local *hukou*), suggesting that the reform could not substantially eliminate resentments about the

³²Chen and Fu (2023) find that big cities' policies that restrict migrant children's access to public schools increase the likelihood that migrants work in the cities alone while leaving their children at home. This suggests that, despite lower migration costs for relocating to small cities (in terms of family unity), migrants are still inclined to move to big cities.

hukou policy. Second, protesting against the *hukou* policy is not the primary cause of observed unrest events. In the CLB data, 72 percent of events were over wage arrears, and 11 percent over job losses.³³ However, we notice that a small number of unrest events that demand social security and housing subsidies from employers may be effectively against the *hukou* policy. As a robustness check, we show that the *hukou* reform reduced labor unrest unrelated to *hukou*, but had a null effect on *hukou*-related unrest (Table B5). Taken together, our results should not be interpreted as driven by a mechanical decline in protests against the *hukou* policy in the wake of the *hukou* reform.

4.3 Additional Robustness Checks

4.3.1 Alternative Standard Errors

In Appendix H.1, we show that our results are robust to alternative standard errors, including clustering by province and Conley standard errors (Conley, 1999).

4.3.2 Alternative Specifications and Estimators

In Appendix H.2, Table H2 and Figure H1, we adopt alternative specifications and estimators to estimate the effect of the *hukou* reform on labor unrest: (i) different forms of the dependent variable (logarithmic and inverse hyperbolic sine transformations); (ii) Poisson regression in light of the non-negative nature of the dependent variable (Silva and Tenreyro, 2006); and (iii) the spatial autoregressive (SAR) model to take into account spatial spillovers. Across specifications and estimators, we consistently find that the *hukou* reform lowered labor unrest rates.

4.3.3 Excluding Potential Outliers

In Appendix H.3, we show that our results are not due to outlier observations. We test whether our results are driven by any particular province by leaving out one province at a time and re-estimating Equation 2. As Figure H2 shows, the estimate is stable to the exclusion of any single province.

In Table H3, we consider the influences of several sets of outliers on the estimated effect of the *hukou* reform. First, we exclude prefectures that never had a labor unrest event recorded by the CLB to ensure that our results are not due to low variation in labor unrest (recorded by the CLB) in reform prefectures. Second, inspired by the “donut-hole RD” exercise, we exclude prefectures near the 3 million cutoff to address potential self-selection into reform status and/or measurement error in reform status resulting from measurement error in urban population. Third, we exclude those 17 prefectures with discrepancies between population-defined and actual reform statuses to avoid the influence of likely endogenous non-compliance. Lastly, following Hansen (2022, pp. 84–86), based

³³Note that an individual protest event can have multiple causes. In total, 77 percent of events in our sample are due to wage arrears and/or job losses.

on goodness-of-fitting, we identify observations that are most influential in our estimation and exclude them to assess the robustness of our results. Regardless of which set of outliers is excluded, we estimate a strong, often more pronounced than baseline effect of the *hukou* reform on decreasing labor unrest.

4.3.4 Covariate Balancing

In Table H4 in Appendix H.4, we address concerns about the heterogeneity between reform and non-reform prefectures. This heterogeneity is reflected in the unbalanced baseline covariates despite the inclusion of polynomials in Table 2. We show that our results survive different strategies to balance baseline covariates: (i) regression adjustments by controlling for interactions between the covariates and year dummies; (ii) balancing the propensity score (probability of being under the reform) predicted by the covariates; and (iii) balancing the *distributions* of covariates using the coarsened exact matching (CEM) proposed by Iacus et al. (2012). Our results survive these strategies to balance covariates.

Summary. To summarize, in this section, we provide robust evidence that the *hukou* reform led to a significant decrease in labor unrest rates. Such a decrease is not a result of population-correlated confounders, an artifact of differential coverage of labor unrest events, or a consequence of population growth. The next section is devoted to investigating mechanisms through which the *hukou* reform influences the occurrence of unrest.

5 Unpacking Mechanisms

Having established that the *hukou* reform reduces labor unrest rates, we now turn to the question of what mechanisms explain our results. As discussed in Section 2.3, the *hukou* reform enables migrants to pursue permanent settlement in their destinations, plausibly creating dependence on the state and in turn deterring participation in labor unrest (which the state dislikes). We corroborate this hypothesis by showing that the *hukou* reform raises migrants' settlement intentions, reflected by longer migration duration. In Section 5.2, we develop a novel econometric approach to quantify the importance of enhanced settlement intentions in explaining the *hukou* reform's effect on decreasing labor unrest.

We want to be explicit that we do not claim that heightened settlement intentions are the only mechanism by which the *hukou* reform impacts unrest rates. In Section 5.3, we discuss other potential mechanisms.

5.1 Migrants' Settlement Intentions

We begin by investigating whether the *hukou* reform enhances migrants' settlement intentions and thus lengthens their duration stay in their destination. Section 5.1.1 describes the data used in our investigation. Section 5.1.2 discusses our empirical strategy, and Section 5.1.3 reports the results.

5.1.1 Data

For the purpose of our investigation, we use the 2015 mini-census. This census includes information on where an individual resided by the end of 2010, 2014, and 2015. This allows us to construct an individual's residential history at three moments in time, and we can infer whether an individual had migrated during one of these periods. For example, we may observe:

$$A, 2010 \rightarrow B, 2014 \rightarrow B, 2015.$$

In this example, we can infer that the person must have migrated between 2010–2014 (from A to B) but not between 2014–2015.³⁴

Using this information, we trace how the *hukou* reform affects a migrant's decision on outmigration from their 2010 place of residence. For this purpose, we restrict the sample to individuals who were migrants in 2010. We define an individual as a migrant if their 2010 residential prefecture differs from their 2015 *hukou* registration prefecture. We rely on this definition because while we observe an individual's residential history, we do not observe the *hukou* registration history. This definition introduces measurement error if an individual changed *hukou* registration between 2010 and 2015. We defer the discussion of how measurement error may influence our results.

5.1.2 Empirical Strategy

Our analysis resembles a survival analysis where the event of interest ("failure") is outmigration from the 2010 location. Specifically, we estimate the following linear probability model (LPM):

$$\Pr\left(Outmigration_{jit} \mid \mathbf{W}_{jit}\right) = \rho (Reform_i \times Post15_t) + \lambda_i + \mu_t + f(\tilde{p}_i; \zeta_{Reform,t}), \quad (5)$$
$$t \in \{2014, 2015\}.$$

³⁴The data do not allow us to identify circular migration. For example, someone recorded as living in A in both 2010 and 2014 may have moved temporarily to B in 2012, which goes unobserved. Consequently, a 2012 migration from A to B would not be measured. However, since circular migration often occurs due to an attachment to the original destination, outmigration captured in the data likely reflects a more permanent departure. This focus aligns with our primary interest in investigating how the *hukou* reform influences such movements.

In Equation 5, the dependent variable, $Outmigration_{j|t}$, is a dummy variable that equals one if individual j has left their 2010 residing prefecture i by year t . Given the nature of our data, we observe this outcome for 2014 and 2015. Equation 5 is estimated using data for these two periods.

$\mathbf{W}_{j|t}$ denotes a set of explanatory variables on the right-hand side. $Reform_i$ is the reform status of 2010 residing prefecture i . $Post15_t$ is a dummy variable that equals one if $t = 2015$ but zero if $t = 2014$. Here, we treat 2015 as the post-reform period while 2014 as the pre-reform period.³⁵ We also include prefecture and year fixed effects as well as polynomial controls. In the spirit of survival analysis, for an individual who decided to leave their initial location k at year t , we drop subsequent observations to focus on that individual's initial outmigration.

Our coefficient of interest, ρ , is estimated by comparing trends in outmigration rates among not-yet-migrated individuals between reform and non-reform prefectures. It thus captures the impact of the *hukou* reform in the initial location on the outmigration rate. We expect ρ to be negative as the *hukou* reform facilitated migrants staying longer in their initial migration destinations.

5.1.3 Results

Table 4 reports estimates of Equation 5. Columns (1)–(3) use all migrants as the estimation sample. Column (1) shows that the estimated ρ is negative. This is consistent with our hypothesis, and the estimate indicates that the *hukou* reform reduces the likelihood of outmigrating from the initial destination by 5.7 percentage points. This effect amounts to 42.9 percent of the average outmigration rate in non-reform prefectures.

We interpret decreased outmigration as reflecting heightened stay intentions caused by the *hukou* reform. However, one competing interpretation is that if migrants in reform prefectures have inherently distinct dynamics of integration into their destination from those in non-reform prefectures, then we would observe them staying longer anyway. To alleviate this concern, we control for origin (*hukou* prefecture) fixed effects to leverage variation within migrants of the same origin (Column (2)). This way, conceptually we compare two migrants of the same origin but subject to distinct trajectories of the *hukou* regime (reform vs. non-reform). This within-origin comparison is arguably cleaner given the importance of origin conditions to migration (Zaiour, 2023). As Column (2) shows, however, including origin fixed effects actually does not markedly change our estimate. Further, to the degree that distinct dynamics of integration are due to differences in individual characteristics, we control for differential dynamics by including interactions between individual covariates and year indicators (Column (3)). The covariates include birth cohort, gender, educational attainment, and employment status. We see that our estimate does not change markedly with the inclusion of these controls, highlighting the importance of intentions to stay. In Columns

³⁵As we only observe the residential prefecture by the end of 2014 in the census data, we can only define outmigration during 2010–2014. However, for those individuals who had ever moved during this period, it is expected that the majority of them should have moved much earlier, possibly before the *hukou* reform took effect in July 2014. For this reason, we argue that this treatment definition is reasonable.

Table 4. The Effect of the *Hukou* Reform on Outmigration

	Outmigration from 2010 residing prefecture				
	(1)	(2)	(3)	(4)	(5)
Reform × Post	-0.057** (0.026)	-0.056** (0.026)	-0.057** (0.027)	-0.071** (0.034)	-0.019 (0.016)
Sample	All migrants	All migrants	All migrants	Rural migrants	Urban migrants
Control mean	0.133	0.133	0.133	0.165	0.089
Prefecture FE	Yes	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes	Yes	Yes
Origin FE		Yes	Yes	Yes	Yes
Individual covariates × Year FE			Yes	Yes	Yes
Observations	100,875	100,875	100,875	58,647	42,228
<i>R</i> ²	0.048	0.087	0.095	0.146	0.066

Note: This table reports the effect of *hukou* reform on the outmigration rate. Individual covariates include birth cohorts, gender, educational attainment, and employment status. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

(4) and (5), we restrict the sample to rural migrants and urban migrants, respectively. We find that decreased outmigration rates are driven by migrants from rural areas. This may be expected: rural migrants tend to face greater barriers to integration into their destinations due to limited wealth, making them more responsive to the institutional relaxation of those barriers. Indeed, we see that rural migrants are twice as likely as urban migrants to leave their initial destinations. As a robustness check, we also estimate a Cox proportional hazard model (common in survival analysis) and find similar results (see Appendix I.1).

Recall that we restrict our sample to migrants in 2010, defined as those whose 2010 residing prefectures differ from their *hukou* prefectures reported in 2015. This definition may misclassify some individuals as migrants in 2010: natives who later migrated and transferred their *hukou* would appear to be migrants in 2010. These misclassified migrants would mechanically exhibit a higher rate of outmigration from the 2010 residing prefectures. However, we argue that our results are not driven by measurement error. First, measurement error should be minimal among rural migrants observed in 2015, because urban-to-rural *hukou* transfers are very rare and even prohibited (Song, 2014), rural migrants should be less likely to have transferred their *hukou* registration. Table 4 shows a strong reform effect among rural migrants, suggesting that measurement error is not a primary driver of our results. Second, we perform a robustness check that excludes plausibly misclassified migrants. Appendix I.2 reports the details. Table I2 shows the estimation results after excluding plausibly misclassified migrants. The estimates are in fact larger than those in Table 4, albeit with larger standard errors due to 30 percent smaller sample sizes. The effects are again driven by rural migrants, indicating that the heterogeneous effects between rural and urban migrants are not due to differential measurement error between the two groups.

In summary, we find that the *hukou* reform significantly reduced outmigration rates, even when we condition on individual characteristics that may relate to integration into the migration destination. The effects are more pronounced among rural migrants who otherwise have a low chance of integration. We conclude that the *hukou* reform had led to heightened settlement intentions.

5.2 Importance of Heightened Settlement Intentions

Thus far, we have shown that the *hukou* reform increases settlement intentions. One natural question is: how much of the *hukou* reform's effect on labor unrest can be attributed to increased settlement intentions?

To answer this question, we need to conduct a causal mediation analysis, i.e., identifying the causal effect of the *hukou* reform that goes through enhancing settlement intentions (*indirect effect*) versus the causal effect that goes through other mechanisms (*direct effect*). This is a rather challenging task. The conventional approach relies on estimating a system of two linear regressions (e.g., [Baron and Kenny, 1986](#); [Cutler and Lleras-Muney, 2010](#)): the first is a regression of the outcome on the treatment, and the second further controls for the mechanism variable on the basis of the first regression; then, one interprets the change in the treatment coefficient as the indirect effect, i.e., the treatment effect mediated by a particular mechanism. However, this approach is subject to an important identification challenge: the mechanism variable is typically not quasi-exogenous; as a result, the mechanism effect on the outcome is not identified, so that the coefficient change is biased for the indirect effect ([Imai et al., 2011](#)). To overcome this challenge, we propose improvements to the conventional approach. In a nutshell, our approach uses an instrumental variable (IV) to identify the mechanism effect on the outcome, and we preserve the simplicity of regression techniques in the conventional approach.

Next, we first briefly discuss our methodology in Section 5.2.1, because it is not commonly implemented in economics literature. We focus on the main intuition, while presenting technical details in Appendix J. Then in Section 5.2.2, we apply the method to our case and investigate the importance of heightened settlement intentions in explaining the *hukou* reform's impact on reducing labor unrest.

5.2.1 Methodology

Basic Setup and Conventional Approach. To illustrate our method for causal mediation, we consider a more general setup. Let i denote the unit of observation. Let Y_i denote the outcome of interest, T_i denote the quasi-exogenous treatment, and M_i denote the mechanism of interest.

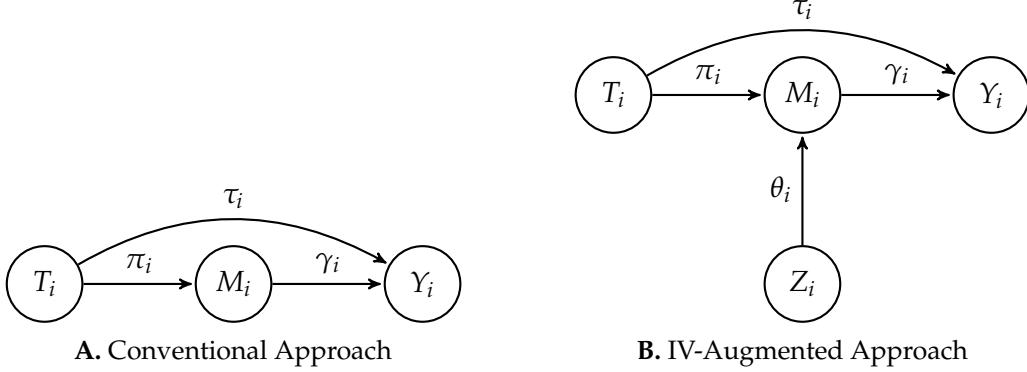

Figure 4. Directed Acyclic Graphs

Figure 4A presents a directed cyclic graph (DAG) for the relations between the three variables.³⁶ Treatment T_i can influence outcome Y_i through two pathways: (i) *direct influence*, with a marginal effect of τ_i , and (ii) *indirect influence* via a certain mechanism M_i , with a marginal effect of $\gamma_i\pi_i$, where π_i is the marginal effect of T_i on M_i , and γ_i is the marginal effect of M_i on Y_i . Note that parameters $(\tau_i, \pi_i, \gamma_i)$, as the subscripts indicate, may vary across i , which extends the homogeneous effect framework in Imai et al. (2011). We now summarize some parameters that are pertinent to our analysis.

DEFINITION 1 (Parameters). Let $E(\cdot)$ be the expectation operator across i .

1. The total effect of T_i on Y_i is defined as $\beta_i \equiv \tau_i + \gamma_i\pi_i$. The average total effect (ATE) is then $E(\beta_i) \equiv E(\tau_i) + E(\gamma_i\pi_i)$.
2. The indirect effect of T_i on Y_i attributable to mechanism M_i is $\gamma_i\pi_i$. The average indirect effect (AIE) is then $E(\gamma_i\pi_i)$.
3. The direct effect of T_i on Y_i is not attributable to mechanism M_i is τ_i . The average direct effect (ADE) is then $E(\tau_i)$.

Note that $ATE = ADE + AIE$. A researcher may be interested not only in the ATE but also in the AIE (and its magnitude relative to the ATE), as this reveals the importance of the mechanism. Therefore, we would be interested in estimating the AIE. Conventionally, this is done by estimating the following two regression models:

$$Y_i = \alpha_1 + \beta T_i + e_{i1}, \quad (6)$$

$$Y_i = \alpha_2 + \tau T_i + \gamma M_i + e_{i2} \quad (7)$$

³⁶We use the DAG here for the ease of presentation. In Appendix J, we provide technical details for our methodology using the potential outcome framework, which is equivalent to the DAG framework (Imbens, 2020).

For illustration, also consider a third regression model:

$$M_i = \alpha_3 + \pi T_i + e_{i3}. \quad (8)$$

For notations, let $\hat{\kappa}$ denote the OLS estimator of κ . Also, to further simplify notations, we do not distinguish between estimators and estimands, i.e., we let $\hat{\kappa}$ equate $\text{plim } \hat{\kappa}$, assuming appropriate asymptotic properties. The conventional approach estimates the AIE by taking the difference in coefficients on T_i between Equations 6 and 7 (Baron and Kenny, 1986), i.e., the estimator is defined as $\widehat{AIE} \equiv \hat{\beta} - \hat{\tau}$. By properties of least squares, the following result holds:

$$\widehat{AIE} \equiv \hat{\beta} - \hat{\tau} = \hat{\gamma} \hat{\pi}. \quad (9)$$

Note that $\hat{\gamma} \hat{\pi}$ is the product of (i) the estimated effect of M_i on Y_i ($\hat{\gamma}$) and (ii) the estimated effect of T_i on M_i ($\hat{\pi}$). This expression helps clarify the challenge of the conventional approach in identifying the AIE. The key challenge here is that $\hat{\gamma}$ from Equation 7 needs to consistently estimate the average effect of M_i on Y_i . This requires that M_i is exogenous conditional on T_i (e.g., Imai et al., 2011; Acharya et al., 2016). That is to say, there are no unobserved confounders related to M_i and Y_i once T_i is conditioned on. It is a strong assumption in many settings. In our context, this can be violated if, for instance, the *hukou* reform changed factors that simultaneously affected settlement intentions and the organization of labor unrest. In addition, as we discuss further later, one may need to assume that either γ_i is homogeneous or $\gamma_i \perp\!\!\!\perp \pi_i$ (Glynn, 2012). This assumption ensures that $AIE = E(\gamma_i \pi_i) = E(\gamma_i)E(\pi_i)$, i.e., the expectation of a product can be written as a product of expectations, and thus, $\widehat{AIE} = \hat{\gamma} \hat{\pi}$ can be consistent for AIE with the exogeneity assumption (see Appendix J.1 for a proof of consistency).

Proposed Approach. To tackle the challenge in identifying the average effect of M_i on Y_i , we propose to use an instrumental variable (IV) for M_i , denoted by Z_i . Therefore, we refer to our approach as an “IV-augmented approach.” We leave technical details in Appendix J.2. Figure 4B visualizes the relationship between variables in our proposed approach. It incorporates Z_i on the basis of Figure 4A. Note that instrument Z_i only affects outcome Y_i indirectly through mechanism M_i , reflecting the exclusion restriction. The marginal effect of Z_i on M_i is θ_i . In Appendix J.2, we prove the following result.

PROPOSITION 1. Suppose: (i) Z_i is a valid IV for M_i , i.e., Z_i is related to M_i and affects Y_i only through M_i ; (ii) the marginal effect of M_i on Y_i , γ_i , is homogeneous; and (iii) each τ_i , γ_i , and π_i is bounded below or above by 0. With M_i instrumented by Z_i , least squares estimators of Equations 6 and 7 satisfy: $\widehat{AIE} \equiv \hat{\beta} - \hat{\tau} = \hat{\gamma} \hat{\pi}$, and

$$\widehat{AIE} = E(\gamma_i \pi_i) \equiv AIE. \quad (10)$$

Proof. See Appendix J.2. ■

Proposition 1 means that our approach to estimating AIE preserves the simplicity of the conventional approach given by Equation 9. That is, we estimate the same system as before: Equation 6 is estimated by OLS, while Equation 7 is estimated by 2SLS with M_i instrumented by Z_i . Then, the difference between treatment coefficients gives an estimator for AIE. Under what assumptions is this procedure valid? First, as in any IV strategies, Z_i needs to be a valid IV for M_i , satisfying the relevance assumption and the exclusion restriction. This ensures that the 2SLS estimator, $\hat{\gamma}$, identifies an average causal effect of M_i on Y_i . Second, we posit that the causal effect of M_i on Y_i , γ_i , is homogeneous. This is a key assumption in our approach. Though strong, it is not uncommon in the literature (Dippel et al., 2022; Dix-Carneiro et al., 2018). It is well known that IV can only identify an average effect of M_i on Y_i within a particular subpopulation, namely, the local average treatment effect (LATE) among compliers (Imbens and Angrist, 1994), which may differ from the population in which the total effect of T_i on Y_i is identified. A homogeneity assumption enables an econometrician to extrapolate the identified LATE from the complier group to the broader population and then evaluate the treatment effect mediated by a mechanism. Nonetheless, in Section 5.2.4, we will discuss the robustness of our conclusion when relaxing this assumption, where we propose a method to bound AIE.

Assumption (iii) is not required for identifying the AIE, but it facilitates interpretations. The reason is as follows. Without sign restrictions, it is likely that the AIE ($E(\gamma_i \pi_i)$) may be zero at the aggregate level, even if the indirect effect ($\gamma_i \pi_i$) is in fact nonzero for most individuals. Since regression coefficients, under necessary assumptions, can only identify average effects, the absence of sign restrictions may restrict their informativeness regarding the role of a mechanism.³⁷

Relevant to our application, a similar result applies to RD designs that identify treatment effects at the cutoff determining treatment status, which we employ in this paper. The following proposition summarizes the result for RD designs.

PROPOSITION 2. *Let r_i denote the running variable. $T_i = \mathbb{1}\{r_i \geq 0\}$. Average effects of interest in Definition 1 are re-defined as those at the cutoff 0: $ATE = E(\beta_i | r_i = 0)$, $AIE = E(\gamma_i \pi_i | r_i = 0)$, and $ADE = E(\tau_i | r_i = 0)$. Least squares estimators of Equations 6 and 7, with M_i instrumented by Z_i and flexible polynomial functions of r_i included, satisfy: $\widehat{AIE} \equiv \hat{\beta} - \hat{\tau} = \hat{\gamma} \hat{\pi}$. Under the same assumptions in Proposition 1,*

$$\widehat{AIE} = E(\gamma_i \pi_i | r_i = 0) \equiv AIE. \quad (11)$$

³⁷Researchers may implicitly make Assumption (iii). For instance, after estimating an average treatment effect on the outcome, a researcher often asserts that the finding can be explained by a mechanism by showing a significant average treatment effect on the mechanism. For this statement to be valid, one typically has a strong belief about the direction of the mechanism's effect on the outcome, although a formal causal mediation analysis may not be performed.

Proof. See Appendix J.3. ■

Next, we apply our methodology to quantify how much of the *hukou* reform's effect on labor unrest can be attributed to heightened settlement intentions, as measured by decreases in outmigration rates.

5.2.2 Empirical Strategy

Estimating Equation. To implement our IV-augmented approach for causal mediation, we convert the panel regression model in the previous analysis to its cross-sectional equivalent. Specifically, we estimate the following models in parallel to Equations 6 and 7:

$$\frac{\Delta Unrest_i}{L_{i,2010}} = \alpha_1 + \beta Reform_i + f(\tilde{p}_i; \zeta_{Reform}) + e_{i1}, \quad (12)$$

$$\frac{\Delta Unrest_i}{L_{i,2010}} = \alpha_2 + \tau Reform_i + \gamma \Delta Outmigration_i + f(\tilde{p}_i; \zeta_{Reform}) + e_{i2}. \quad (13)$$

In the two models, the dependent variable, $\frac{\Delta Unrest_i}{L_{i,2010}} = (\sum_{t=2014}^{2015} \frac{Unrest_{it}}{L_{i,2010}})/2 - (\sum_{t=2011}^{2013} \frac{Unrest_{it}}{L_{i,2010}})/3$, captures the change in the average annual unrest rate from the pre-reform period 2011–2013 to the post-reform period 2014–2015. We measure the change between 2011 and 2015 because it aligns with the time frame in which we can measure outmigration rates in census data. With the difference transformation, the estimated β from Equation 12 is numerically identical to that from Equation 2, i.e., the estimate reported in Column (1) of Table 3.

$\Delta Outmigration_i$ in Equation 13 is the mechanism variable of interest (" M_i "). It is the change in the annual outmigration rate from the pre-reform period to the post-reform period:

$$\Delta Outmigration_i = Outmigration_{i,2014-2015} - Outmigration_{i,2010-2014}, \quad (14)$$

where $Outmigration_{ip}$ denotes the annual outmigration rate in prefecture i during period p , which we calculate using census data. Recall that in the 2015 census, we can observe a migrant's residing prefectures by the end of 2010, 2014, and 2015. The calculation of $Outmigration_{i,2014-2015}$ is straightforward: it is the fraction of migrants who resided in prefecture i in 2014 but had moved to another prefecture by 2015, relative to all migrants residing in prefecture i in 2014. To calculate $Outmigration_{i,2010-2014}$, we first calculate the overall outmigration rate during the period 2010–2014 and convert it to an annual term so that it is comparable to $Outmigration_{i,2014-2015}$.³⁸ We calculate

³⁸The conversion is done as follows. Let q denote the overall outmigration rate during the period 2010–2014. Assume a constant hazard rate h , that is, the probability of outmigration per unit of time conditional on not year outmigrating. Therefore, $q = 1 - e^{-4h}$; we can solve for $h = -\ln(1 - q)^{1/4}$. This allows us to calculate outmigration rates of four one-year intervals between 2010 and 2014. $Outmigration_{i,2010-2014}$ is the weighted average of the four annual outmigration rates, using as weights the sizes of not-yet-outmigrating migrants: $Outmigration_{i,2010-2014} = \frac{\sum_{k=0}^3 e^{-kh}(1-e^{-kh})}{\sum_{k=0}^3 e^{-kh}} = 1 - e^{-h}$.

these outmigration rates among rural migrants, as they are the groups more affected by the *hukou* reform.

Instrumental Variable. We are interested in how the estimated coefficient on $Reform_i$ changes when $\Delta Outmigration_i$ is instrumented and included in the regression, namely, $\hat{\beta} - \hat{\tau}$. Under the conditions outlined in Proposition 2, $\hat{\beta} - \hat{\tau}$ can be interpreted as the effect of the *hukou* reform on labor unrest through enhancing settlement intentions, or equivalently, through decreasing outmigration rates.

To invoke this interpretation, we need a valid IV for $\Delta Outmigration_i$. Our IV strategy leverages external pull factors of outmigration. Existing literature has documented that economic conditions at origins are relevant to migration decisions (Zaiour, 2023; Imbert et al., 2022; Karadja and Prawitz, 2019).³⁹ Reassuringly, in our migrants sample, we observe that 88 percent of migrants who eventually left their 2010 destinations returned to their home prefectures, suggesting that the origin is an important outside option when migrants decide whether to stay in their destination. We exploit variation in trade shocks to migrants' origins as a pull factor of outmigration.

To construct the IV, following Campante et al. (2023), we first measure the trade shock to a prefecture h in a shift-share (Bartik) fashion:

$$TradeShock_{ht} = \sum_k \underbrace{\frac{X_{hk,2010}^{CN}}{L_{h,2000}}}_{\text{share}} \times \underbrace{\frac{\Delta X_{kt}^{ROW}}{X_{k,2010}^{CN}}}_{\text{shift}}. \quad (15)$$

In this expression, $X_{hk,2010}^{CN}$ is prefecture h 's exports of industry k (6-digit Harmonized System level);⁴⁰ $X_{k,2010}^{CN}$ is the national aggregate exports of industry k ; $\Delta X_{kt}^{ROW} = X_{kt}^{ROW} - X_{k,t-1}^{ROW}$ is the increase/decrease in exports within the rest of the world (less China; ROW in short) in year t .⁴¹ The "shift" component, $\frac{\Delta X_{kt}^{ROW}}{X_{k,2010}^{CN}}$, is the growth in global demand for product k in year t , relative to industry size of product k in China in 2010. It is apportioned to prefectures by the "share" term, $\frac{X_{hk,2010}^{CN}}{L_{h,2000}}$, per-worker export value of industry k in prefecture h ; this captures predetermined specialization patterns.⁴² Thus, $TradeShock_{ht}$ can be interpreted as an average worker's gains or losses due to global trade fluctuations. To be a valid exogenous pull factor, $TradeShock_{ht}$ should be (i) uncorrelated with other factors that may affect return migration and (ii) predictive of return migration. For the first condition, as $TradeShock_{ht}$ exploits aggregate trade shocks in the rest of the world, it is not likely to pick up local conditions within China. More formally, as Borusyak

³⁹Zaiour (2023) shows that homicide in Mexico reduces returns of Mexican migrants from the US to Mexico. Imbert et al. (2022) use agricultural income shocks at origins to instrument for rural-to-urban migration in China. Similarly, Karadja and Prawitz (2019) exploit local frost shocks to predict emigration from Sweden to the US in the late 19th and the early 20th centuries.

⁴⁰As in Campante et al. (2023), we consider only manufacturing industries.

⁴¹ $X_{hk,2010}^{CN}$ and $X_{k,2010}^{CN}$ are measured using Chinese customs data from 2010. ΔX_{kt}^{ROW} is measured using the UN Comtrade database. All variables are in 1,000 dollars.

⁴²As in Campante et al. (2023), the working-age population (25–54 years old) is measured in 2000 to avoid simultaneity bias.

et al. (2022) shows, the exogeneity of $TradeShock_{ht}$ rests on the exogeneity of the product-level shock $\frac{\Delta X_{kt}^{ROW}}{X_{k,2010}^{CN}}$: high shock industries do not systematically concentrate in prefectures with particular characteristics. In Appendix K.1, we perform balance checks proposed by Borusyak et al. (2022) and show that $\frac{\Delta X_{kt}^{ROW}}{X_{k,2010}^{CN}}$ can be regarded as good as randomly assigned across Chinese prefectures. To shed light on the second condition, in Appendix K.2, we show a strong causal relationship between origin trade shocks and outmigration at the individual level.

In a second step of constructing the IV, we aggregate $TradeShock_{ht}$ to a destination prefecture i . The IV is expressed as a shift-share variable:

$$Z_i = \sum_h s_{h \rightarrow i} \times TradeShock_{h,2015} = \sum_k \underbrace{\left(\sum_h s_{h \rightarrow i} s_{hk} \right)}_{\text{share}} \underbrace{\frac{\Delta X_{k,2015}^{ROW}}{X_{k,2000}^{CN}}}_{\text{shift}}. \quad (16)$$

We consider trade shocks in 2015 (relative to 2014). $s_{h \rightarrow i}$ is the share of migrants who originated from prefecture h and lived in prefecture i relative to all migrants who lived in prefecture i , which we measure using migration patterns in 2010. Therefore, Z_i represents global demand fluctuations that an average migrant in prefecture i faced. To be a valid IV, Z_i must meet an exclusion restriction: it only affects labor unrest through the outmigration rate. The exclusion restriction is violated if high-shock industries concentrate in places that tend to send migrants to prefectures with certain factors that themselves independently affect labor unrest. In Appendix K.3, we show that Z_i passes balance tests proposed by Borusyak et al. (2022). Reassuringly, industry-level trade shocks, $\Delta X_{k,2015}^{ROW}/X_{k,2000}^{CN}$, are orthogonal to exposure-weighted average destination characteristics, including lagged population growth, lagged GDP growth, lagged fiscal expenditure growth (total, social security, and public security), as well baseline variables in 2010 (the male share, migrant share, construction/manufacturing/trasportation employment share, and internet users share). We also conduct several additional robustness checks. Figure 5 shows a strong positive relationship between Z_i and $\Delta Outmigration_i$ (F statistic = 16.126), consistent with the findings at the individual level (cf. Appendix K.2).

5.2.3 Results

Main Findings. Table 5 presents the results of the causal mediation analysis, with visualization in Figure 6. Column (1) shows the estimates of Equation 12. In Column (2), we implement the conventional approach for causal mediation analysis by directly adding $\Delta Outmigration_i$ to the specification from Column (1). We observe a significant positive association between outmigration and unrest, suggesting that increased settlement intentions may reduce unrest. Additionally, the coefficient on $Reform_i$ in Column (2) attenuates by 9.1 percent compared to Column (1). Interpreting the estimated coefficient on $\Delta Outmigration_i$ as causal, this change implies that heightened settlement intentions explain 9.1 percent of the *hukou* reform's total effect on labor unrest.

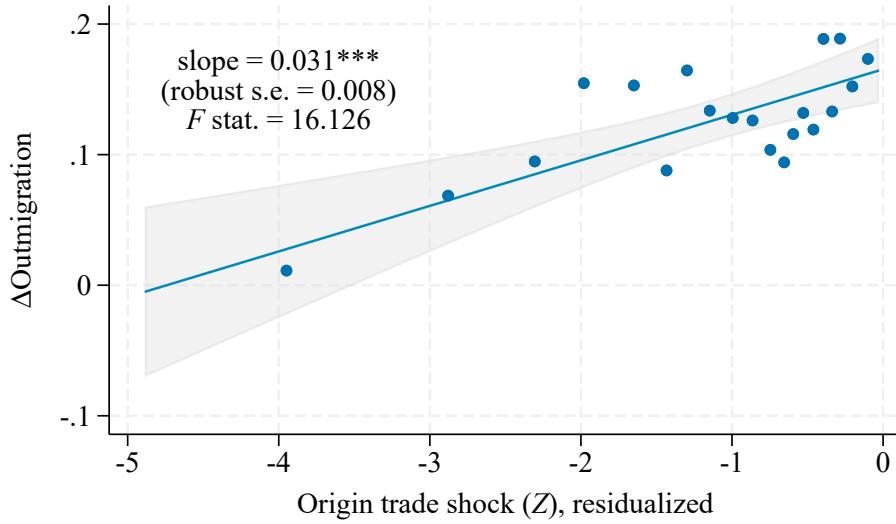

Figure 5. Origin Trade Shocks and Outmigration Rates

Note: This figure plots the changes in the outmigration rate ($\Delta\text{Outmigration}_i$) against average trade shocks at origins of migrants in a destination (Z_i , partialing out variation attributed to reform status and polynomials of urban population). The binscatter plot is created using the data-driven method to estimate conditional means proposed by [Cattaneo et al. \(2024\)](#). The fitted line is created using all observations (rather than just binscatter points).

Table 5. Hukou Reform, Outmigration, and Labor Unrest

	DV: $\Delta\text{Unrest}/L$, 2011–2015		
	(1) Baseline	(2) Mediation-OLS	(3) Mediation-IV
Reform [β or τ]	-1.047** (0.518)	-0.951* (0.535)	-0.387 (0.740)
$\Delta\text{Outmigration}$ [γ]		1.689** (0.680)	11.651*** (4.077)
% Total effect explained		0.091	0.630
Effective F stat.			16.126
tF 95% CI for γ			[0.299, 23.003]
% IV-OLS gap in γ due to endogeneity			0.991
Observations	287	287	287

Note: This table reports causal mediation analysis that quantifies the importance of the settlement intentions mechanism, as captured by the outmigration rate. Column (1) reports the baseline results. Column (2) represents the conventional approach. Column (3) uses the IV-augmented approach. The effective F statistic is calculated following [Olea and Pflueger \(2013\)](#). tF 95 percent confidence interval follows [Lee et al. \(2022\)](#). The IV-OLS gap is decomposed using the methodology by [Ishimaru \(2024\)](#). Robust standard errors are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

In Column (3), we apply our approach that instruments outmigration using migrants' origin trade shocks. As Figure 5 shows, negative trade shocks strongly predict a reduction in outmigration rates. The first-stage strength is confirmed by an effective F statistic of 16.126 ([Olea and Pflueger,](#)

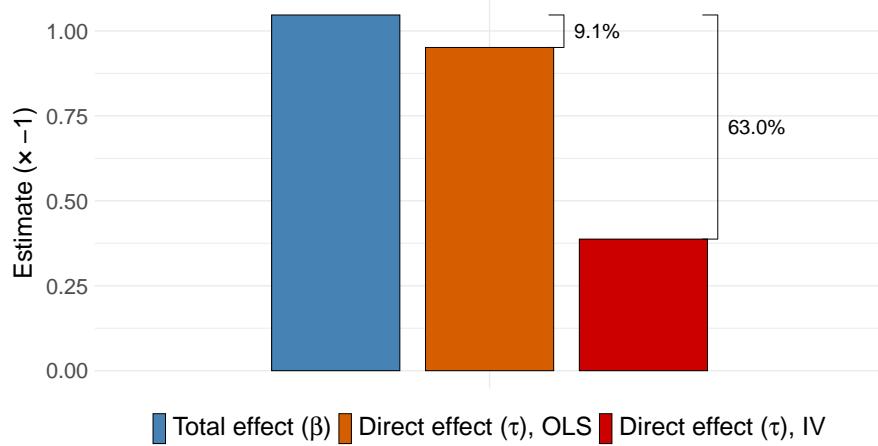

Figure 6. Mediation Visualized

2013). In Column (3), we find that a low outmigration rate significantly reduces labor unrest. The estimate remains statistically significant even if we implement the robust tF inference for IV proposed by Lee et al. (2022). By Proposition 2, we can conclude that 63 percent of the total effect of the *hukou* reform on unrest can be attributed to heightened settlement intentions.⁴³

The IV-augmented approach implies a higher share of the total effect that can be explained by heightened settlement intentions compared to the conventional approach. The increase is due to inflation in the estimated coefficient on $\Delta Outmigration_i$, $\hat{\gamma}$, after instrumentation. Suppose that the IV is valid, the *empirical* IV-OLS gap can arise from two sources: (i) endogeneity bias (due to omitted variables and/or measurement error) purged by IV, and (ii) the different weighting schemes used by IV and OLS aggregate potentially nonlinear effects.⁴⁴ We apply the decomposition method developed by Ishimaru (2024) to calculate the contribution of each source. The results indicate that nearly all the IV-OLS gap can be attributed to endogeneity bias purged, and the increased importance of the mechanism after instrumentation is not mechanically driven by a different weighting scheme.⁴⁵

⁴³For completeness, we also conduct a similar mediation analysis for the change in labor unrest during 2011–2019. In Table B6, the IV-augmented approach shows that heightened settlement intentions, measured from 2010–2015, can explain 32.2 percent of the decrease in labor unrest from 2011–2019 resulting from the *hukou* reform. This magnitude is notably smaller than that for the 2011–2015 period. The attenuation can be because $\Delta Outmigration_i$ does not fully capture migrants' settlement intentions over the longer term, or $\Delta Outmigration_i$ has zero effects in the longer term as migrants have successfully attained local *hukou*.

⁴⁴In theory, homogeneity of γ_i assumes away (ii). But the least squares estimation does not impose this assumption. Thus, when the assumption does not hold, the empirical IV-OLS gap can still be driven by differences in how IV and OLS weight nonlinear effects. For instance, imagine a scenario where $\Delta Outmigration_i$ is purely exogenous so that endogeneity bias is zero, and its impact on $\frac{\Delta Unrest_i}{L_i, 2010}$ is nonlinear, but the nonlinearity does not differ across prefectures. In this case, OLS and IV would aggregate nonlinear effects differently, and the IV-OLS gap is entirely due to differences in weighting schemes.

⁴⁵The endogeneity bias in OLS is negative. We argue that this may be driven by attenuation bias due to measurement error. Omitted variables bias tends to be positive: high outmigration rates may be associated with poor conditions that should have increased labor unrest.

Robustness Checks. Our results rely on the validity of the IV, i.e., origin trade shocks affect labor unrest *only* through their effects on outmigration. The balance tests provide some confidence in this assumption. We conduct three additional checks in Appendix K.4.

First, one may be concerned about the channels through which origin trade shocks can affect labor unrest. For instance, origin trade shocks may be correlated with destination trade shocks if migrants are short-distance and regional industrial structures are similar. The other concern is that besides outmigration, origin trade shocks may induce in-migration; the population growth may influence the occurrence of labor unrest. However, Table K4 and Figure K1 show that our results are robust to controlling for destination trade shocks and population growth as robustness checks. If anything, the results accentuate the importance of the outmigration channel.

Second, one may be concerned that trade shocks at some origins can have significant spatial spillover impacts on labor unrest at the destination. To address this issue, we attempt two alternative ways to construct the IV: (i) we exclude migrants from origins within 100km; and (ii) we exclude migrants from regional economic centers, e.g., provincial capitals and four provincial-level municipalities. More broadly, following Borusyak and Hull (2023), we use a recentered version of Z_i that subtracts the expected origin trade shock for prefecture i , which captures potential spillovers and other forms of omitted variables due to nonrandomness of networks. Table K5 and Figure K2 present the results of these exercises. From them, we can still conclude that the enhanced settlement intention is a quantitatively important mechanism.

Third, we use the methodology developed by Conley et al. (2012) to assess how exogenous the IV is. Specifically, we test whether we can conclude that outmigration has a significant effect on labor unrest even if allowing for some violations of the exclusion restriction. Figure K3 presents the results. We find that the positive relationship between outmigration and unrest holds even under substantial violations of the exclusion restriction. This supports that outmigration is a plausible mechanism through which the *hukou* reform influences labor unrest.

5.2.4 Sensitivity Test

The results above rely on the assumption that the mechanism effect on the outcome, γ_i , is constant. With this assumption, we conclude that the heightened settlement intentions can explain 63 percent of the effect of the *hukou* reform on labor unrest. This is nevertheless a strong assumption. In this section, we explore the resilience of our conclusion to relaxing the homogeneous mechanism effect assumption.

Methodology. To substantiate the main intuition, assume $\gamma_i \perp\!\!\!\perp \pi_i$. Note that homogeneity of γ_i implies this condition, but not vice versa. Therefore, γ_i is allowed to be heterogeneous across i . In Appendix J.4, we present a general, albeit more complicated framework without assuming

$\gamma_i \perp\!\!\!\perp \pi_i$, and Appendix K.5 presents the results using the general framework, which yields a similar conclusion.

The following expression illustrates the issue when we introduce heterogeneity of γ_i (see Appendix J for derivations):⁴⁶

$$\widehat{AIE} = \hat{\gamma} \cdot E(\pi_i) \quad (17)$$

$$= \underbrace{E(\gamma_i \pi_i)}_{\text{AIE}} + \underbrace{[\hat{\gamma} - E(\gamma_i)] E(\pi_i)}_{\text{IV bias}} \quad (18)$$

Let us inspect Equation 18. The equality holds if $E(\gamma_i \pi_i) - E(\gamma_i)E(\pi_i) = \text{Cov}(\gamma_i, \pi_i) = 0$, which is granted by $\gamma_i \perp\!\!\!\perp \pi_i$. It writes \widehat{AIE} as the summation of two components: the first term $E(\gamma_i \pi_i)$ is AIE, the parameter of interest, and the second term is a bias term, which is referred to as “IV bias” as it is the gap between the IV-identified effect and the average mechanism effect. Clearly, \widehat{AIE} identifies AIE only if $\hat{\gamma} = E(\gamma_i)$. The IV estimand $\hat{\gamma}$ identifies a LATE:

$$\hat{\gamma} = E(\phi_i \gamma_i). \quad (19)$$

$\phi_i = \frac{\tilde{Z}_i M_i}{E(\tilde{Z}_i M_i)}$ is the weight placed on γ_i , where \tilde{Z}_i is the residual of the linear projection of Z_i onto T_i (and possibly other controls). Clearly, in general, $\hat{\gamma} \neq E(\gamma_i)$. One sufficient condition is that γ_i is constant across i . Without this assumption, \widehat{AIE} in general is biased for AIE, and the bias can be either upward or downward.

Ideally, if we know $E(\gamma_i)$, we can remove the bias by subtracting $[\hat{\gamma} - E(\gamma_i)] \hat{\pi}$ from \widehat{AIE} . However, this is infeasible because $E(\gamma_i)$ is unknown. To investigate the degree to which \widehat{AIE} is informative about AIE, we impose minimal distributional assumptions that pin down $E(\gamma_i)$, and then adjust \widehat{AIE} to obtain a new estimand that identifies AIE, that is,

$$\widehat{\widehat{AIE}} = \widehat{AIE} - [\hat{\gamma} - E(\gamma_i)] \hat{\pi}, \quad (20)$$

provided that the distributional assumptions are true. Although this approach does not directly estimate the true value of AIE, it gives a *gradient* of $\widehat{\widehat{AIE}}$ —the possible consistent estimator of AIE—with respect to $[\hat{\gamma} - E(\gamma_i)]$ —the IV bias. If the gradient is relatively flat, i.e., $\widehat{\widehat{AIE}}$, then \widehat{AIE} can still be informative about AIE.

Specifically, note that

$$\hat{\gamma} - E(\gamma_i) = E(\phi_i \gamma_i) - E(\gamma_i) = \rho_{\phi\gamma} \sigma_\phi \sigma_\gamma \quad (21)$$

⁴⁶A similar result holds for RD designs by assuming that γ_i and π_i are independent of the running variable r_i or replacing unconditional moments in the expression with conditional moments at $r_i = 0$ (see Appendix J).

where $\sigma_\phi = SD(\phi_i)$, $\sigma_\gamma = SD(\gamma_i)$, and $\rho_{\phi\gamma} = \text{Corr}(\phi_i, \gamma_i)$. The gap $\hat{\gamma} - E(\gamma_i)$ is determined by the joint distribution of (ϕ_i, γ_i) . We impose assumptions on the distribution of (ϕ_i, γ_i) to derive a consistent estimator for AIE. The following proposition summarizes our result.

PROPOSITION 3. *Suppose that γ_i is uniformly distributed and $\gamma_i \perp\!\!\!\perp \pi_i$. For RD designs, additionally suppose $\{\gamma_i, \pi_i\} \perp\!\!\!\perp r_i$. For every given $\rho_{\phi\gamma} = \text{Corr}(\phi_i, \gamma_i)$, under the same set of assumptions in Proposition 1,*

$$\hat{\gamma} - E(\gamma_i) = \frac{\rho_{\phi\gamma}\hat{\sigma}_\phi\hat{\gamma}}{\sqrt{3}\text{sgn}(\gamma_i) + \rho_{\phi\gamma}\hat{\sigma}_\phi}, \quad (22)$$

$$\widehat{\widehat{AIE}} = \frac{\sqrt{3}\text{sgn}(\gamma_i)\hat{\gamma}}{\sqrt{3}\text{sgn}(\gamma_i) + \rho_{\phi\gamma}\hat{\sigma}_\phi} \hat{\pi} = AIE, \quad (23)$$

where $\hat{\sigma}_\phi = \sqrt{\frac{1}{n} \sum_{i=1}^n \left(\frac{\tilde{Z}_i M_i}{\frac{1}{n} \sum_{i=1}^n \tilde{Z}_i M_i} - 1 \right)^2}$, and $\text{sgn}(\cdot)$ is the sign function that satisfies: $\text{sgn}(x) = 1$ if $x > 0$, $\text{sgn}(x) = 0$ if $x = 0$, and $\text{sgn}(x) = -1$ if $x < 0$.

Proof. See Appendix J.4. ■

Proposition 3 implies that for each given $\rho_{\phi\gamma}$, $\rho_{\phi\gamma}$ governs the size of $\hat{\gamma} - E(\gamma_i)$, and $\widehat{\widehat{AIE}}$ identifies AIE. In a special case $\rho_{\phi\gamma} = 0$, $\hat{\gamma} - E(\gamma_i) = 0$, and $\widehat{\widehat{AIE}} = \widehat{AIE}$. By Proposition 3, we can plot the gradient of $\widehat{\widehat{AIE}}$ with respect to $\rho_{\phi\gamma}$ to see how the estimator for AIE varies by heterogeneity imposed on γ_i . In addition, because the correlation coefficient $\rho_{\phi\gamma}$ is bounded, the gradient can provide bounds for AIE.

Results. Now we apply Proposition 3 to our case. We suppose that $\gamma_i \geq 0$ and $\pi_i \leq 0$, i.e., a high outmigration rate (equivalently, low settlement intention) universally increases labor unrest, and the *hukou* reform reduces the outmigration rate (or raises settlement intentions). We consider the scenario where $0 \leq \rho_{\phi\gamma} \leq 1$, so \widehat{AIE} may have *overestimated* AIE by assuming constant γ_i , and $\widehat{\widehat{AIE}}$ adjusts the overestimation for each given $\rho_{\phi\gamma}$.

Figure 7 reports the relationship between the share of total effect explained by the mechanism $ShareExplained = \widehat{\widehat{AIE}}/\beta$ and the indicator of IV bias $\rho_{\phi\gamma}$. We see that, when $\rho_{\phi\gamma} = 0$, we obtain the highest *ShareExplained* of 63 percent, as reported in Table 5. As $\rho_{\phi\gamma}$ increases and IV bias becomes larger due to the effect heterogeneity, *ShareExplained* declines. However, the decline is not very steep. Even in the most extreme case, $\rho_{\phi\gamma}$, the settlement intentions mechanism can still explain 16 percent of the effect of the *hukou* reform on labor unrest. We regard this as a nontrivial fraction. Since there is no information on the actual distribution of (ϕ_i, γ_i) , this lower bound tends to be overly conservative by letting the IV bias be maximal. In reality, $\rho_{\phi\gamma}$ may not be that large.

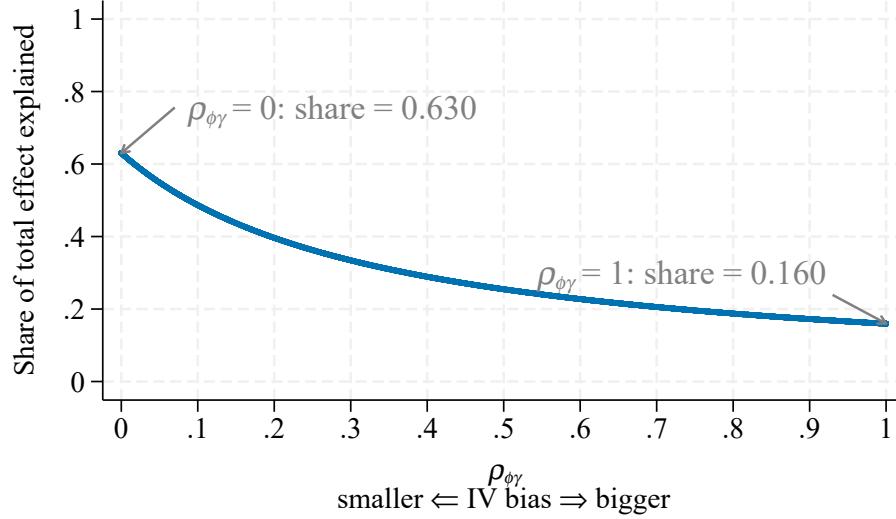

Figure 7. Sensitivity Test for Causal Mediation Analysis

Note: This figure presents the sensitivity test for causal mediation analysis. $\rho_{\phi\gamma}$ is the correlation coefficient between weights (ϕ_i) that IV places on heterogeneous effects (γ_i). A larger $\rho_{\phi\gamma}$ leads to a larger IV bias, i.e., the difference between IV-identified LATE for compliers ($\hat{\gamma} = E(\phi_i \gamma_i)$) and the average effect for the entire population ($E(\gamma_i)$). We consider $\rho_{\phi\gamma} \in [0, 1]$ such that the baseline mediation results overstate the importance of outmigration by imposing $\rho_{\phi\gamma} = 0$. For each given $\rho_{\phi\gamma}$, by Proposition 3, we derive the share of total effect explained by outmigration.

In conclusion, the results above demonstrate the resilience of the settlement intentions mechanism. We conclude that heightened settlement intentions play a nontrivial role in mediating the *hukou* reform's effect of reducing labor unrest, and they can explain up to 63 percent of the decrease in labor unrest.

5.2.5 Corroborative Evidence: Heterogeneity by Migrants' Geographic Distance to Origins and Cultural Distance to Natives

The *hukou* reform reduced the *institutional* barriers to integration into the migration destination. However, migrants may respond differently to this change in institutional barriers due to integration barriers in other dimensions. We exploit variation in these dimensions to further shed light on the importance of settlement intentions.

Geographic Distance to Home. Migrants may prefer to live in places closer to their origins because of proximity to (extended) families, similar cultures, similar climate, etc. Therefore, it stands to reason that migrants in destinations closer to their origins should increase their settlement intentions more after the reform, and those destinations should also see a greater decrease in labor unrest. To test this hypothesis, we first calculate migrants' average distance to origins for each prefecture i , denoted by D_i^M (measured in 2010). We then re-estimate Equation 3 for prefectures with high migrant distance to origins (D_i^M above the median) and those with low migrant distance to origins (D_i^M below the median). Figure 8A reports the results. Consistent with our hypothesis,

the reform reduces labor unrest more in places where migrants are closer to their origins. The confidence intervals are wide, however.

Cultural Distance to Natives. Migrants face *cultural* barriers to integration, such as differences in dialects, food preferences, lifestyles, and social norms compared to the natives. Therefore, the *hukou* reform should have a larger effect of enhancing settlement intentions for migrants who have a smaller cultural distance to the native population of their migration destination, and we may expect that the *hukou* reform had a more pronounced effect in places where migrants on average have a smaller cultural distance.

To test this heterogeneity by cultural distance, we follow [Guarnieri \(2025\)](#) to measure cultural distance by linguistic distance. As a big nation, China has many languages and dialects, and even the official language, Mandarin, has several variants. According to the classification by *The Language Atlas of China* ([Lavely and Berman, 2012](#)), there are 106 languages and dialects in China, and Mandarin has 44 variants. As in [Guarnieri \(2025\)](#), we can calculate the linguistic distance between two prefectures h and i , denoted by LD_{hi} (see Appendix E for construction details). Then, we aggregate LD_{hi} to obtain an average migrant's linguistic distance in prefecture i :

$$LD_i^M = \sum_h s_{h \rightarrow i} LD_{hi}, \quad (24)$$

where $s_{h \rightarrow i}$ is the share of migrants from prefecture h to prefecture i , relative to all migrants in prefecture i (measured in 2010), as in Equation 16.

We then separately estimate the effect of the *hukou* reform on labor unrest for prefectures with high migrant cultural distance (LD_i^M above the median) and those with low migrant cultural distance (LD_i^M below the median). Figure 8B shows that the reduction in labor unrest is entirely driven by prefectures where migrants have a low cultural distance and thus are more prompted to stay by the *hukou* reform. However, one should take this corroborative evidence with caution, as the cultural distance may be related to other factors that independently generate differential reform effects.

Taken together, the results above for heterogeneous effects suggest the importance of settlement intentions: the *hukou* reform indeed has a larger effect on labor unrest in places where migrants' settlement intentions should increase more in the wake of the reform.

5.3 Other Mechanisms

Thus far, we have presented evidence supporting the role of heightened settlement intentions. Of course, we do not claim that this is the sole mechanism of action. In this section, we investigate other potentially important mechanisms through which the *hukou* reform leads to decreased labor

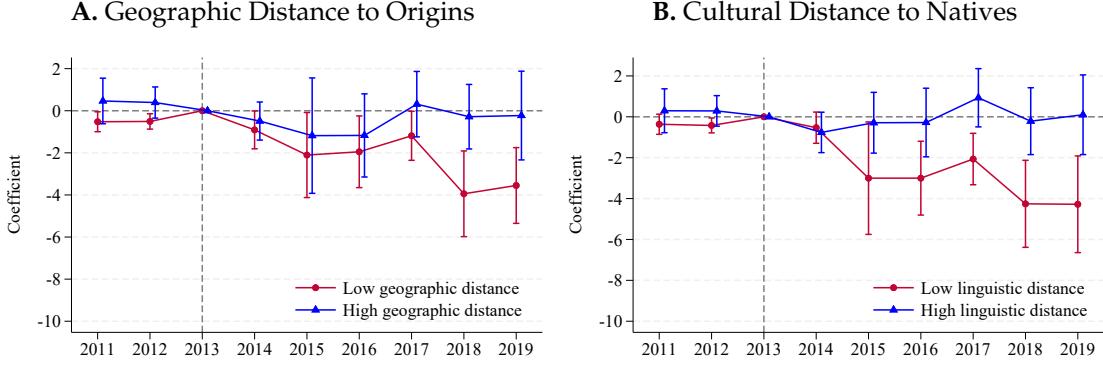

Figure 8. Heterogeneous Reform Effects on Labor Unrest by Migrants’ Geographic Distance to Origins and Cultural Distance to Natives

Note: This figure presents the heterogeneous effects of the *hukou* reform on labor unrest by migrants’ geographic distance to home or cultural distance to natives. In Panel A, the “low geographic distance migrants” group includes prefectures with a D_i^M (migrants’ average distance to origins) below the median, and the “high geographic distance migrants” group includes prefectures with a D_i^M above the median. In Panel B, the “low linguistic distance migrants” group includes prefectures with an LD_i^M (migrants’ linguistic distance to natives) below the median, and the “high linguistic distance migrants” group includes prefectures with an LD_i^M above the median. The solid dots are point estimates, and the caps are 95 percent confidence intervals.

unrest, including (i) compositional changes among migrants, (ii) benefits available to migrants, and (iii) governments’ social control.

5.3.1 Compositional Changes

One possible mechanism is that the *hukou* reform may alter the characteristics of migrants as it induces population movements. If certain characteristics are strongly associated with participation in unrest—for instance, if migrants with certain characteristics are more likely to participate in unrest because they have low costs of participation or tend to work in industries with poor working conditions—then we would observe decreased unrest rates after the *hukou* reform. However, the compositional shift may not be a first-order explanation of our findings as we do not find that the *hukou* reform had significant impacts on population sizes (see Section 4.2.2). It is only relevant if there is churning within the migrant pool, where the overall size remains constant but the composition changes.

We investigate the role of compositional changes by estimating the impacts of the *hukou* reform on several characteristics of migrants. We use a large, nationally representative survey of migrants between 2011–2018, the China Migrants Dynamic Survey (CMDS). In the CMDS, we observe gender, ethnicity, age, marital status, educational attainment, whether the migration is cross-province, and living arrangements. We estimate Equation 2 at the individual level where the dependent variable is the migrant’s characteristic of interest. Because the CMDS is conducted annually in May, for these regressions, we treat years from 2015 onward as post-reform.

Table 6 reports the results. We examine the composition of all migrants as well as new arrivals (defined as those who arrived in the past year). We do not detect any significant effect of the *hukou* reform on migrants' characteristics. We also do not see significant effects of the *hukou* reform on migrants' family (re)unification in terms of co-residence with spouses or children, whose presence may affect migrants' cost of engaging in unrest. These results suggest that compositional changes cannot play a major role in explaining our findings.

Note: This table presents the effects of *hukou* reform on migrants' characteristics. All regressions control for prefecture and year fixed effects and polynomials of centered log urban population. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

5.3.2 Migrants' Well-being

One may hypothesize that the *hukou* reform improved treatment of migrants, thereby reducing the likelihood of labor unrest. We examine this possibility using information from the CMDS.

Columns (1)–(3) of Table 7 first investigate if there are improvements in migrants' labor market outcomes. We consider three measures: workforce participation, earned wages, and employees' access to social security (ASS; only available from the CMDS in 2011, 2013, and 2016). We do not find significant effects on these labor market outcomes, suggesting that reduced labor unrest is not due to improved labor market outcomes.⁴⁷ The lack of labor market effects also indicates that the decreased labor unrest we detect should not result from an increase in employers' market power. One may propose that the *hukou* reform, by increasing labor supply, can give employers greater market power, which they can use to deter workers' unrest. If so, wages should also decrease,

⁴⁷A recent paper by An et al. (2024) finds significant negative effects of the *hukou* reform on wages and ASS. However, their definition of reform status and empirical strategy (DiD) are different from ours. In Appendix L, we replicate their results and compare them under a series of different empirical decisions. We find that their results are due to the use of a DiD strategy that simply compares more populous prefectures vs. less populous prefectures. In Section 4.1, we show why such a comparison can be questionable.

which we do not observe in the data. This is not surprising given that we do not find that the *hukou* reform increased population growth (see Section 4.2.2).

Given the lack of discernible changes in benefits available to migrants (at least during the short period that we study), it is unlikely that our findings are a mechanical consequence of reform-induced improvements in migrants' well-being.

Table 7. *Hukou* Reform on Available Benefits

	(1)	(2)	(3)
	Working	Log wage	ASS
Reform × Post	-0.003 (0.007)	0.003 (0.019)	0.006 (0.029)

Observations	990,912	810,696	162,239

Note: This table presents the effects of *hukou* reform on benefits available to migrants. The dependent variables are: an indicator for working currently, log wages, and access to social security (ASS). All regressions control for prefecture and year fixed effects and polynomials of centered log urban population. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

5.3.3 Governments' Social Control

Another explanation for why the *hukou* reform reduces labor unrest is that the *hukou* reform may induce local officials to tighten social control. This would occur if officials *believed* population inflows would threaten social stability.

In Table 8, we examine this possibility using several measures of local governments' efforts to maintain social stability. In Columns (1) and (2), we see null effects of the *hukou* reform on local governments' expenditures on public security (police) and social security, indicating the reform did not lead to material investments in social control.

However, local governments prioritizing maintenance of social stability may divert more bureaucratic apparatus manpower to the issue instead of additional financial investment. To test if local governments paid more attention to stability maintenance, we use the share of stability-related keywords in the subsequent year's government work report (GWR). GWRs are comprehensive policy documents that local government heads present annually to local People's Congresses, in which they summarize accomplishments from the previous year and lay out work plans for the

next.⁴⁸ However, Column (3) shows that there is no discernible shift of policy focus toward stability maintenance in the text of these documents.

Finally, if our finding is driven by tighter social control, we would expect a higher fraction of unrest events repressed by the government, despite the overall drop in unrest occurrences. The CLB documents the government response for about 30 percent of reported events. Using this information, we calculate the share of unrest events known to have been repressed by the government (in the form of detention of workers and police intervention).⁴⁹ Column (4) shows that the *hukou* reform had no significant impact on the share of unrest events that were repressed.

Taken together, the tightening of social control does not appear to be the main mechanism underpinning our findings.

Table 8. *Hukou* Reform and Autocratic Control

	(1) Log expenditure on public security	(2) Log expenditure on social security	(3) Share of stability related keywords	(4) Share of unrest events known to be repressed
Reform × Post	-0.000 (0.035)	0.058 (0.050)	0.011 (0.009)	0.088 (0.077)
Control mean	12.908	13.316	0.086	0.228
Sample period	2007–2017	2007–2017	2010–2015	2011–2019
No. prefectures	287	287	287	285
Observations	3,064	3,091	1,676	1,806

Note: This table presents the effects of *hukou* reform on autocratic control. Dependent variables are: log expenditure on public security (police), log expenditure on social security, share of stability-related mentions in next year's government work report, and share of unrest events repressed. All regressions control for prefecture and year fixed effects and polynomials of centered log urban population. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

5.4 Discussion

Throughout this section, we discuss the mechanisms through which the *hukou* reform reduces labor unrest. One mechanism we highlight is heightened settlement intentions, which deters participation in unrest due to fears of losing the opportunity of permanent settlement. Our novel causal mediation analysis shows that this mechanism is nontrivial and can account for 63 percent of the *hukou* reform's total effect on labor unrest during the period under study.

It is worth considering the group and time window for which the settlement intentions mechanism can play out. This mechanism primarily applies to migrants who desire to settle in their destination permanently but have not yet transferred their *hukou*, meaning that our

⁴⁸The GWR text has been adopted in the literature to measure Chinese officials' policy focus (Jiang, 2018; Jiang et al., 2019; Jiang and Zhang, 2020).

⁴⁹This measure is missing if there are no unrest events in a given prefecture and year.

mechanism may be more relevant in the short term. Indeed, in Section 5.2.3 we notice that settlement intentions, as measured by outmigration rates, have better explanatory power for the *hukou* reform’s effect on unrest in the immediate term (2011–2015) than in the long term (2011–2019). In Figure 2, we find that the *hukou* reform had a persistent effect of reducing labor unrest. The *hukou* reform has therefore likely stimulated lasting changes in patterns of labor unrest. Our results suggest that such lasting changes are unrelated to migrants’ characteristics, benefits available to migrants, or governments’ social control strategies. This suggests that the *hukou* reform may change other deeper factors relevant to labor unrest. One possibility is that by permitting some migrants to integrate into their destinations or simply raising migrants’ settlement intentions, the *hukou* reform may destroy the cohesion of social networks, which is conducive to unrest activities. As we do not have micro-level information on the organization of labor unrest, we leave it to future researchers to explore how the *hukou* reform shapes the dynamics of labor unrest in the long term.

6 Conclusions

This paper investigates the causal relationship between integration policy and social stability. By examining the impact of China’s *hukou* reform on labor unrest, we find that, contrary to the common concern about increased social turmoil, lowering integration barriers may actually enhance social stability. Our findings suggest that heightened settlement intentions among migrants are a key mechanism: in seeking to secure the state-controlled opportunity for permanent settlement introduced by the reform, migrants may be discouraged from participating in unrest.

Broadly speaking, we view our results as highlighting a source of state capacity and a force behind social changes. The dependence on the state constitutes the state’s coercive power to induce citizens’ compliance (Hassan et al., 2022; Albertus, 2015)—in our case, migrants rely on the state for permanent settlement in their destinations. In this regard, weakening dependence on the state may facilitate civil disobedience and the momentum of social changes.

We close this paper by noting two limitations that may offer interesting avenues for future research. First, as noted in Section 5.4, migrants’ heightened settlement intentions may not explain all the observed reduction in labor unrest. It is an open question of how migrants behave once they have established permanent settlement. Second, our paper primarily focuses on migrants’ behaviors, partly because the literature has widely documented that migrants are the major participants in labor unrest. However, it remains likely that natives also react to the reform’s initiative and integration of migrants, as suggested by evidence on immigration’s electoral effects among existing citizens (Mayda et al., 2022). Understanding these issues can be an interesting avenue for future research on migration policy and its sociopolitical implications.

A Additional Figures

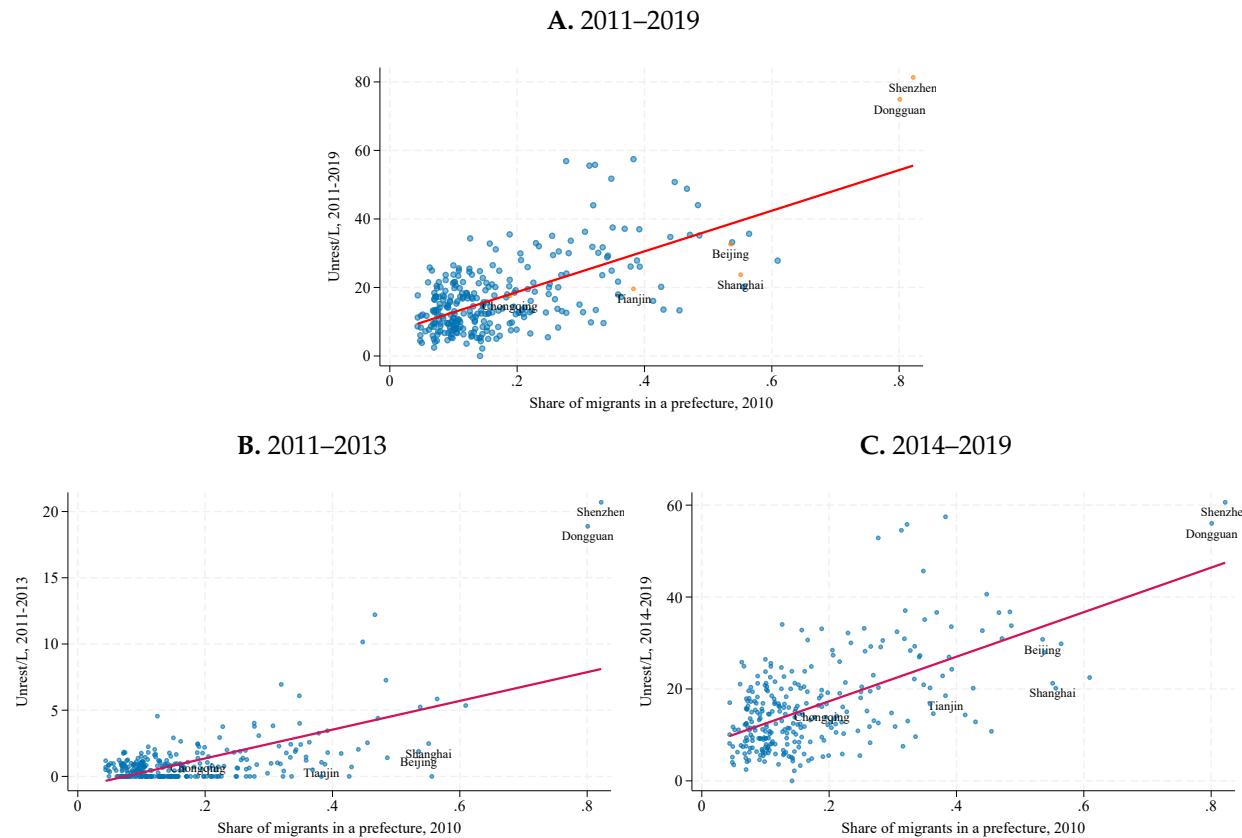

Figure A1. Migrant Share and Labor Unrest Rate

Note: This figure depicts the relationship between the migrant share and the labor unrest rate. The migrant share is measured using the 2010 population census. It is defined as the share of the population whose *hukou* registration is not in the current prefecture. The labor unrest rate is measured using the China Labor Bulletin: it is defined as the total number of unrest events per million working-age population. Panel A is for the period of 2011–2019, Panel B is for the pre-reform period, 2011–2013, and Panel C is for the post-reform period, 2014–2019.

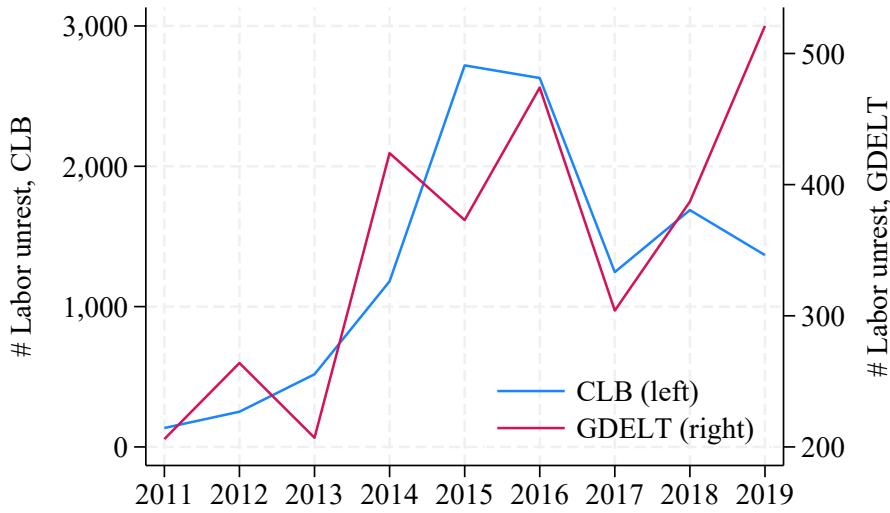

Figure A2. Labor Unrest in CLB and GDELT

Note: This figure presents the national trends of labor unrest events recorded in CLB and GDELT. In GDELT, an event is defined as a labor unrest event if it is classified into the “Protest” category and involves labor.

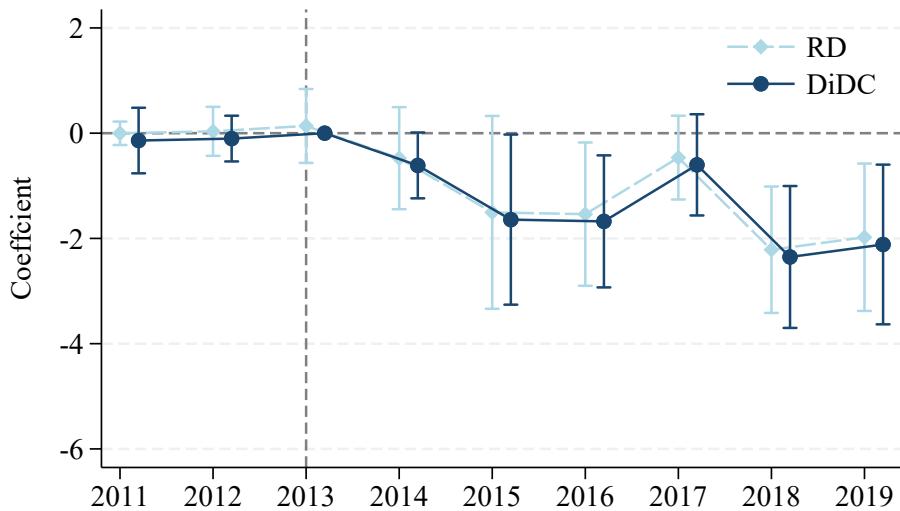

Figure A3. Effects of the *Hukou* Reform on Labor Unrest: RD Estimates

Note: For each period t , we estimate the RD specification: $\frac{Unrest_{it}}{L_{i,2010}} = \alpha_t + \beta_t Reform_i + \zeta_{Reform,t} \hat{p}_i + \nu_{it}$. The coefficients of interest are β_t 's, which capture the differences in occurrences of labor unrest between reform and non-reform prefectures. In the figure, the solid points are point estimates of β_t 's, and the caps are the 95 percent confidence intervals.

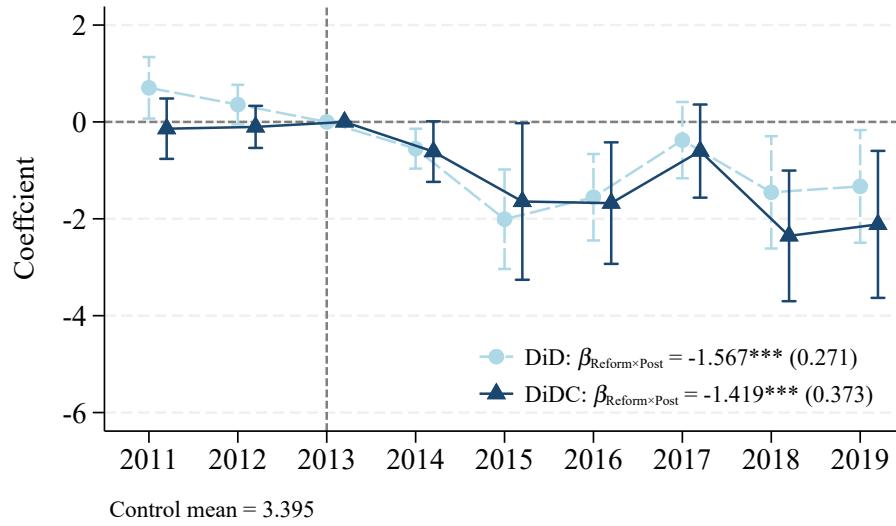

Figure A4. Effects of the *Hukou* Reform on Labor Unrest: DiD vs. DiDC Estimates

Note: This figure presents event-study estimates of DiD and DiDC designs. DiD is implemented by Equation 2 without the inclusion of polynomials. DiDC is implemented by Equation 2. In the figure, the solid points are point estimates of β_t 's, and the caps are the 95 percent confidence intervals.

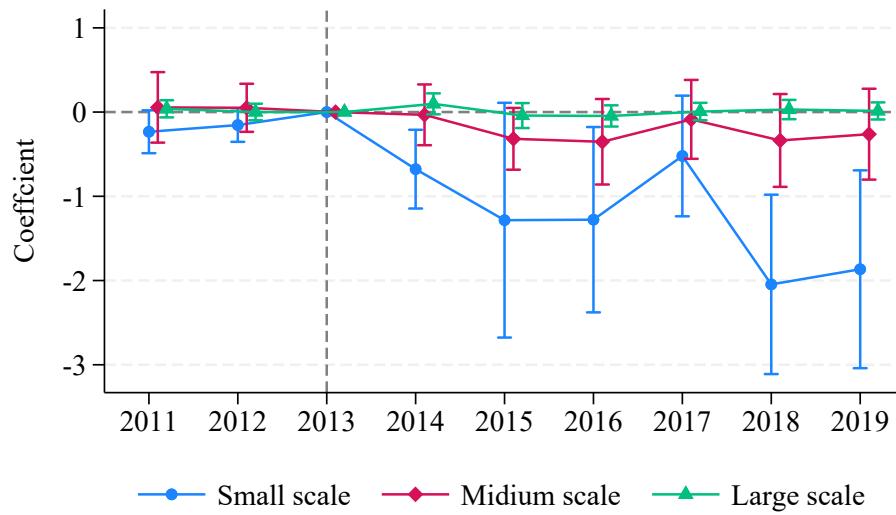

Figure A5. Effects of the *Hukou* Reform on Labor Unrest by Scale

Note: This figure presents event-study estimates of the effects of the *hukou* reform on labor unrest by scale: small scale (1–100 participants), middle scale (101–1,000 participants), and large scale (1,001–10,000 participants). In the figure, the solid dots are point estimates, and the caps are the 95 percent confidence intervals.

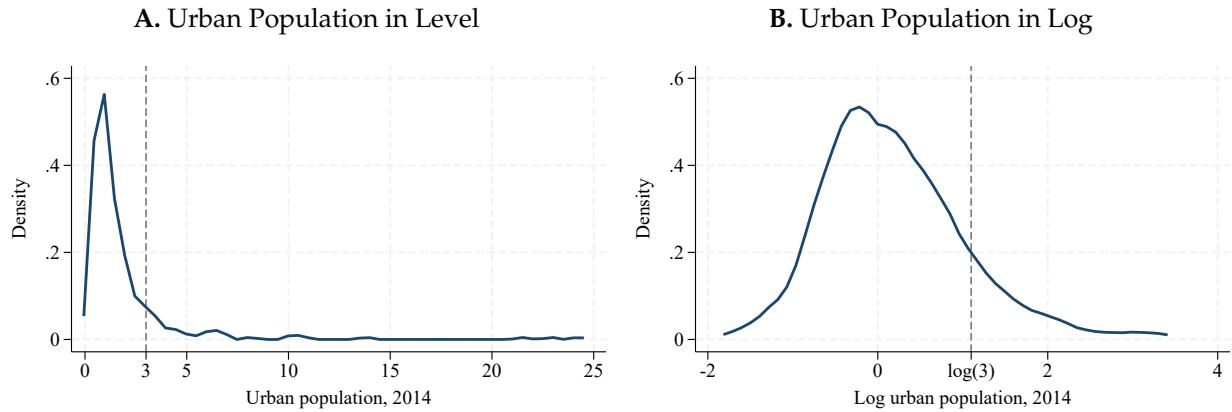

Figure A6. Distribution of Urban Population

Note: This figure depicts the distributions of urban population in level and in log. The vertical lines the reform cutoff, 3 and $\log(3)$, respectively.

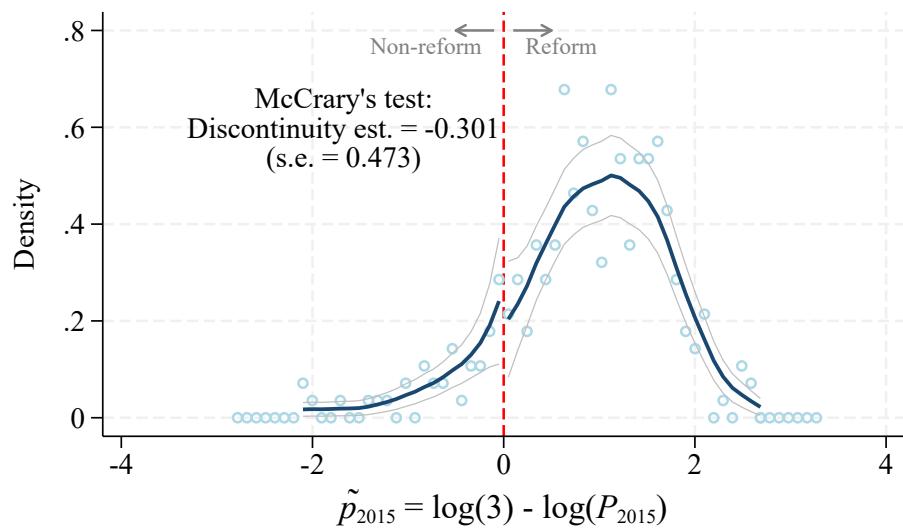

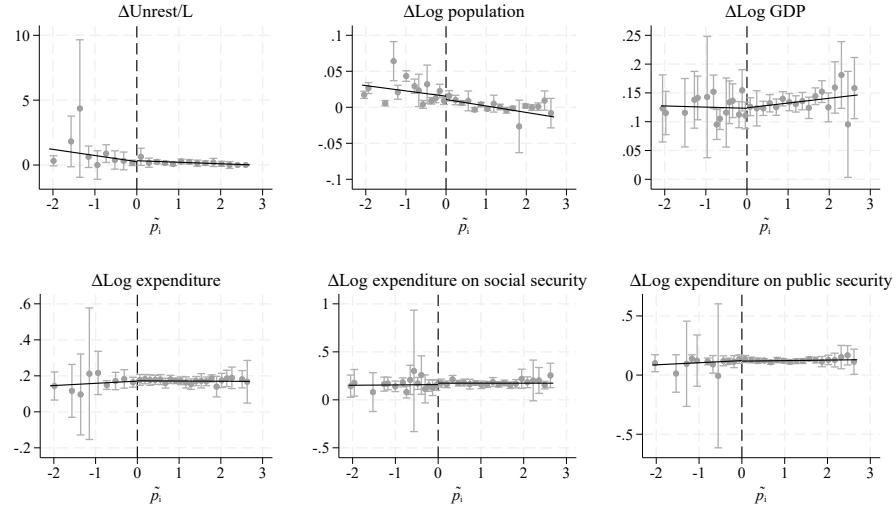

Figure A7. Density of Centered Log Urban Population in 2015

Note: This figure A7 depicts the density of $\tilde{p}_{i,2015} = \log(3) - \log(P_{i,2015})$. We report McCrary's test for density discontinuity at 0.

A. Pretrends

B. Predetermined Characteristics

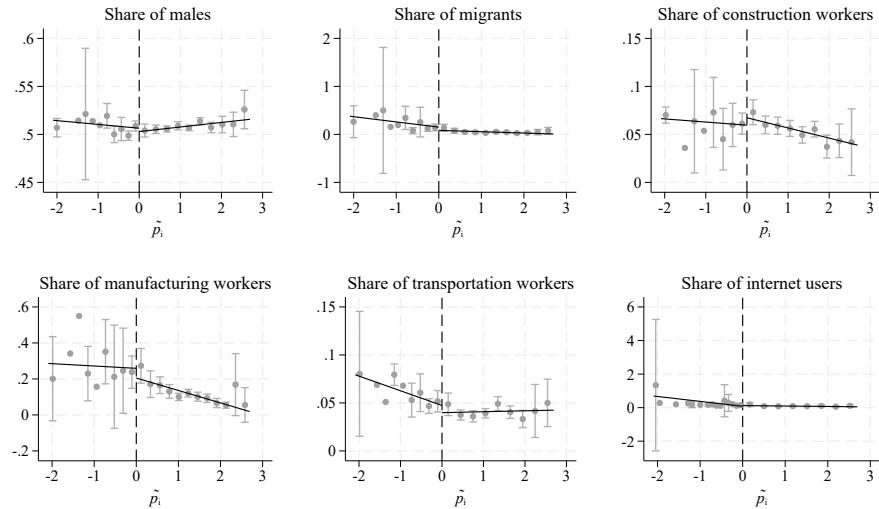

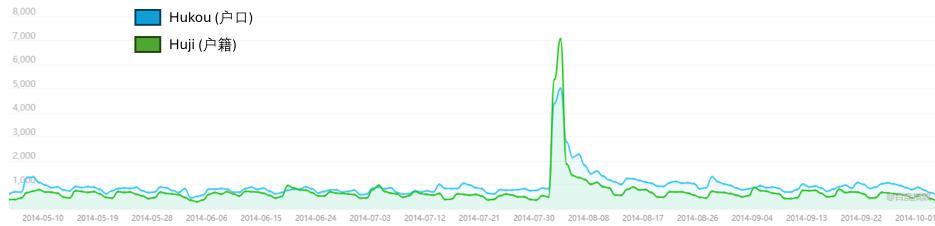

Figure A8. RD Plots of Pre-reform Covariates

Notes: This figure visually presents balance tests of pre-reform covariates. Panel A examines pretrends in unrest rate and a set of variables that may be conducive to unrest. Panel B examines a set of predetermined characteristics.

A. Hukou-Related Terms

B. Hukou Reform-Related Terms

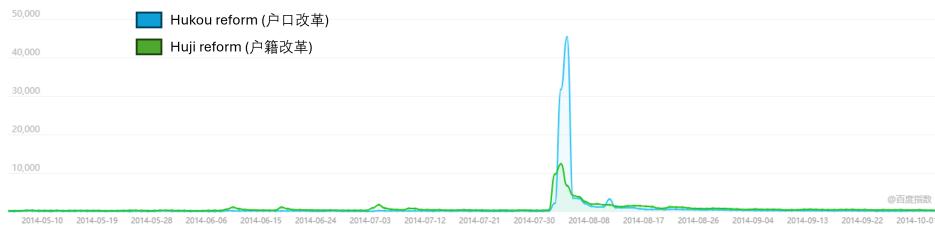

Figure A9. Baidu Searches for *Hukou*- and *Hukou*-Reform-Related Terms

Notes: This figure presents search volumes on Baidu for *hukou*-related terms. Panel A shows searches for “*hukou*” (户口) and its synonym, “*huji*” (户籍). Panel B shows searches for terms related to policies: “*hukou reform*” (户口改革) and “*huji reform*” (户籍改革).

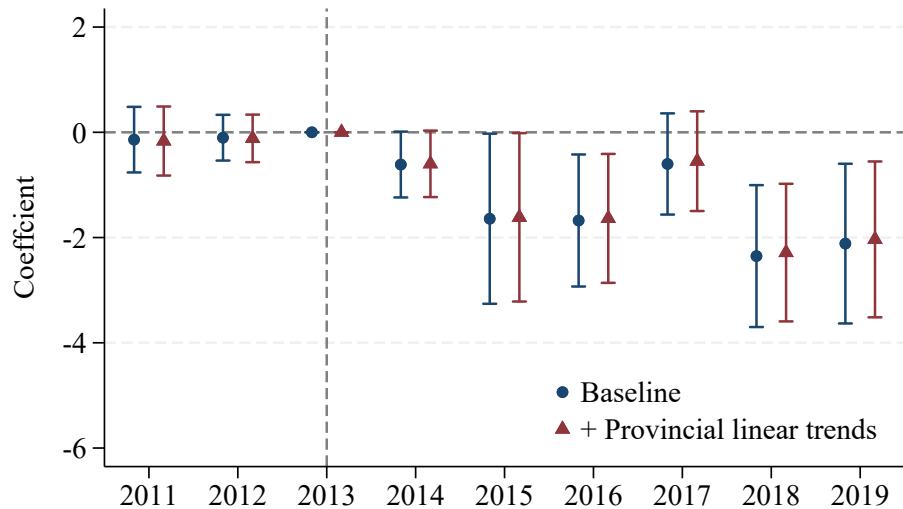

Figure A10. Dynamic Effects: Controlling for Provincial Linear Trends

Note: This figure presents the event-study estimates from Equation 3 (baseline) and the estimates after controlling for province-specific linear trends. The solid dots are point estimates, and the caps are the 95 percent confidence intervals constructed based on standard errors clustered at the prefecture level.

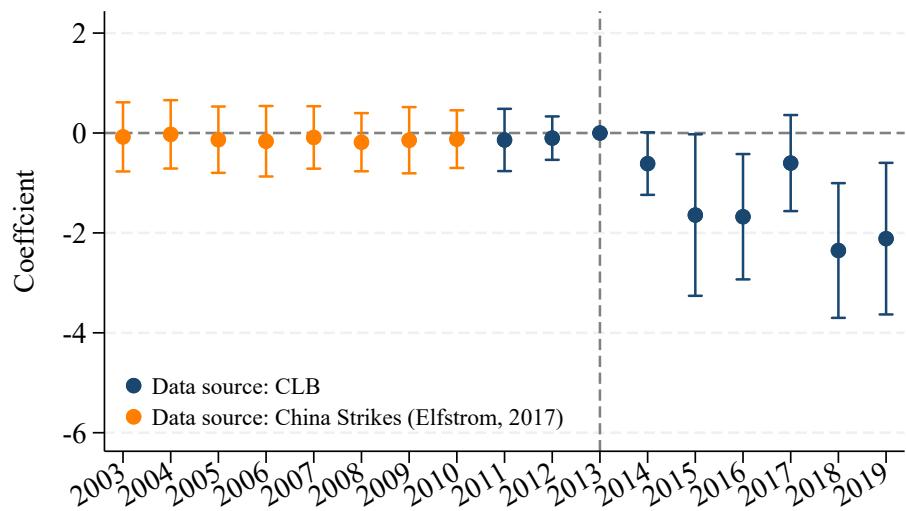

Figure A11. Dynamic Effects: Additional Pretrends

Note: This figure presents the event-study estimates from Equation 3 with extended pre-reform observations. We obtain data on labor unrest between 2003–2010 from *China Strikes* database Elfstrom (2017). The solid dots are point estimates, and the caps are the 95 percent confidence intervals constructed based on standard errors clustered at the prefecture level.

B Additional Tables

Table B1. Results Using Polynomials of Logarithmic vs. Level Urban Population

	(1)	(2)	(3)
	Unrest/L	Unrest/L	Unrest/L
Reform × Post	-1.567*** (0.271)	-1.419*** (0.373)	-1.237** (0.385)
Control mean	3.395	3.395	3.395
Prefecture FE	Yes	Yes	Yes
Year FE	Yes	Yes	Yes
Polynomials (log)		Yes	
Polynomials (level)			Yes
Observations	2,583	2,583	2,583

Note: This table presents the results for the effect of *hukou* reform on labor unrest rates. The first two columns are identical to the first two columns reported in Table 3. Column (1) reports the two-way fixed effects estimate. Column (2) includes polynomials of centered log urban population, that is, $\log(3) - \log(P_{i,2014})$. Column (3) includes polynomials of the centered urban population, i.e., $3 - P_{i,2014}$. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

Table B2. Promotion Prospect and Urban Population Change

	Dependent: $\Delta \log(P)$, 2013–2014		
	(1)	(2)	(3)
	All	$P_{2013} < 3M$	$P_{2013} > 3M$
Promotion prospect	-0.026 (0.082)	-0.024 (0.091)	-0.203 (0.279)
Observations	287	251	36

Note: This table reports the association between a prefectural party secretary's promotion prospect and the growth in urban population from 2013 and 2014 as observed in the UCSY. The promotion prospect index is estimated following Wang et al. (2020): the higher, the better prospect. We report the association for the entire sample (287 prefectures), prefectures with less than 3 million urban population before the reform initiative (2013), and prefectures with more than 3 million urban population before the reform initiative. Robust standard errors are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

Table B3. The Effect of the *Hukou* Reform on Labor Unrest by Scale

	(1) Samll-scale unrest/L 1–100	(2) Middle-scale unrest/L 101–1,000	(3) Large-scale unrest/L 1,001–10,000
Reform × Post	-1.149*** (0.337)	-0.267** (0.103)	-0.003 (0.031)
Prefecture FE	Yes	Yes	Yes
Year FE	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes
Observations	2,583	2,583	2,583
R ²	0.588	0.369	0.251

Note: This table presents the results for the effect of *hukou* reform on labor unrest by event scale. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

Table B4. Examining the Role of Labor NGOs

	(1) Unrest/L	(2) Unrest/L	(3) Unrest/L	(4) Unrest/L	(5) Unrest/L
Reform × Post	-1.419*** (0.373)	-1.348*** (0.370)	-1.515*** (0.389)	-1.431*** (0.449)	-1.464*** (0.386)
Prefecture FE	Yes	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes	Yes	Yes
Log distance to HK × year FE		Yes			
Sample: distance to HK \geq 500km			Yes		
Sample: distance to HK \geq 1,000km				Yes	
Sample: Guangdong province dropped					Yes
Observations	2,583	2,583	2,304	1,755	2,403
R ²	0.601	0.607	0.586	0.602	0.586

Note: This table examines the role of labor NGOs in explaining the effects of the *hukou* reform on labor unrest. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

Table B5. Excluding Welfare-Related Labor Unrest

	(1)	(2)	(3)
	Unrest/L	(Benefit-unrelated Unrest)/L	(Benefit-related Unrest)/L
Reform × Post	-1.419*** (0.373)	-1.342*** (0.353)	-0.077 (0.051)
Control mean	3.395	3.138	0.257
Prefecture FE	Yes	Yes	Yes
Year FE	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes
Observations	2,583	2,583	2,583

Note: This table presents the effect of the *hukou* reform on labor unrest that is not directly related to *hukou* policy itself. Column (1) reports the baseline that looks at all types of unrest. Column (2) excludes unrest events that are due to demands for social security and housing subsidies, as reported in CLB. In contrast, Column (3) looks at unrest events that are due to demands for social security and housing subsidies. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

Table B6. *Hukou* Reform, Outmigration, and Labor Unrest: 2011–2019

	DV: Δ Unrest/L, 2011–2019		
	(1) Baseline	(2) Mediation-OLS	(3) Mediation-IV
Reform [β or τ]	-1.419*** (0.370)	-1.316*** (0.370)	-0.963** (0.472)
Δ Outmigration [γ]		1.834*** (0.484)	8.061** (3.246)
% Total effect explained		0.073	0.322
Effective F stat.			16.126
tF 95% CI for γ			[-0.978, 17.099]
% IV-OLS gap in γ due to endogeneity			0.951
Observations	287	287	287

Note: This table reports causal mediation analysis that quantifies the importance of the settlement intentions mechanism, as captured by the outmigration rate. Column (1) reports the baseline results. Column (2) represents the conventional approach. Column (3) uses the IV-augmented approach. The effective F statistic is calculated following Olea and Pflueger (2013). tF 95 percent confidence interval follows Lee et al. (2022). The IV-OLS gap is decomposed using the methodology by Ishimaru (2024). Robust standard errors are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

C Conceptual Model: Settlement and Unrest Participation

In this section, we present a simple conceptual model to clarify the linkage between settlement plans and unrest participation. Our modeling draws upon insights from literature on temporary migration (for a review, see [Dustmann and Görlach, 2016](#)).

C.1 Model Setup

Consider a migrant in destination d . She has a two-period horizon: the current period (period 1) and the future (period 2). This migrant's lifetime utility is written as:

$$V = u_1 + \beta u_2, \quad (\text{C1})$$

where u_t is the utility in period $t \in \{1, 2\}$, which we specify in detail below, and β is the discount factor.

Period 1 Utility. In period 1, the migrant receives basic earnings w . However, there is one component of income that depends on unrest participation, for example, wage arrears, the resolution of which requires substantive negotiations, possibly by expressive and even violent means.¹ We let $e \geq 0$ denote the level of engagement in unrest. Its marginal return is $a > 0$. However, participation in unrest incurs some cost, which can be due to simple psychological stress, time cost, or even government repression. The cost is given by $\frac{1}{2}\gamma e^2$. The cost function is convex in e , and its magnitude is governed by parameter $\gamma > 0$. Collecting these terms gives the utility in period 1:

$$u_1 = w + ae - \frac{1}{2}\gamma e^2. \quad (\text{C2})$$

Period 2 Utility. In period 2, the migrant may either return to his origin o or stay in destination d . The utility of returning home is normalized to be zero. For ease of discussion below, this is labeled as $u_{2o} = 0$.

In contrast, the utility of staying in the destination is:

$$u_{2d} = x - c - \frac{1}{2}\kappa e^2. \quad (\text{C3})$$

x is the present value of continuing to stay in destination d , which may include earnings, local public services, and taste. However, to stay, a migrant has to bear some cost that consists of two parts. The first part, denoted by c , is the exogenous fixed cost of settlement. It includes all kinds of movement costs, and importantly, institutional barriers of *hukou* transfers that one has to overcome. The other part of the cost is associated with unrest participation in the first period. A migrant with

¹In fact, wage arrears are a reason for 70.58% unrest events recorded in CLB data during 2011–2019.

unrest history may find it harder to settle, because of, for instance, government retaliation that makes settlement impossible or employer retaliation that imposes challenges in satisfying *hukou* transfer requirements.

In summary, a migrant's utility in period 2 depends on where he lives. Let r be a binary variable r that equals one if staying. Then,

$$u_2 = ru_{2d} + (1 - r)u_{2o} = r \left(x - c - \frac{1}{2}\kappa e^2 \right). \quad (\text{C4})$$

Migrant's Problem. In period 1, in anticipation of the future benefits and costs, a migrant decides migration plan r and chooses unrest participating level e . Thus, the migrant's problem is:

$$\begin{aligned} \mathcal{V} &= \max_{e,r} V = u_1 + \beta u_2 \\ &= w + ae - \frac{1}{2}\gamma e^2 + \beta r \left(x - c - \frac{1}{2}\kappa e^2 \right). \end{aligned} \quad (\text{C5})$$

C.2 Results

We solve the model by first finding the optimal e for $r = 1$ and $r = 0$, and then comparing the resulting lifetime utility between two scenarios.

If $r = 1$, by first order conditions (FOCs), it is easy to see the optimal unrest participating level is, $e_1 = \frac{a}{\gamma + \kappa}$. Thus, the lifetime utility is

$$\mathcal{V}_1 = w + e_1 + \beta x - \frac{1}{2}(\gamma + \beta\kappa)e_1^2 - \beta c. \quad (\text{C6})$$

When $r = 0$, by FOCs, the optimal unrest participating level is $e_0 = \frac{a}{\gamma}$. Then, the lifetime utility is

$$\mathcal{V}_0 = w + e_0 - \frac{1}{2}\gamma e_0^2. \quad (\text{C7})$$

Taken together, a migrant would plan on staying, namely, $r = 1$, if

$$\mathcal{V}_1 > \mathcal{V}_0 \quad (\text{C8})$$

$$x > c + \frac{a^2\kappa}{2\gamma(\gamma + \beta\kappa)} \quad (\text{C9})$$

At the aggregate level, the share for an individual migrant to stay is

$$p \equiv \Pr(r = 1) = 1 - F \left[c + \frac{a^2\kappa}{2\gamma(\gamma + \beta\kappa)} \right]. \quad (\text{C10})$$

The aggregate level of unrest is

$$\mathcal{E} \equiv E(e) = pe_1 + (1-p)e_0 = \frac{a}{\gamma} \left(1 - \frac{p\beta\kappa}{\gamma + \beta\kappa} \right). \quad (\text{C11})$$

RESULT 1. $\frac{\partial p}{\partial c} < 0$ and $\frac{\partial \mathcal{E}}{\partial c} > 0$. The hukou reform induces more migrants to stay in the destination, thus, it reduces the aggregate level of unrest.

Proof. Take partial derivatives:

$$\frac{\partial p}{\partial c} = -f \left[c + \frac{a^2\kappa}{2\gamma(\gamma + \beta\kappa)} \right] < 0, \quad (\text{C12})$$

$$\frac{\partial \mathcal{E}}{\partial c} = -\frac{a\beta\kappa}{\gamma(\gamma + \beta\kappa)} \frac{\partial p}{\partial c} > 0. \quad (\text{C13})$$

■

D Verifying the Definition of Reform Status

To verify the population-based definition of reform status, we extensively collect official documents published by local governments regarding the reform, carefully read them, and code up a prefecture's reform status based on the content for comparison. The documents are collected from government websites, media outlets, and a database of *hukou* reforms by [Zhang and Lu \(2019\)](#).

The convention of policy-making in China is that each level of government, adapting to local conditions, would issue implementation guidelines to follow the upper-level government's guidelines. Typically, the guidelines become more specific about provisions when they get to lower levels. In the case we study, after the central government launched the *hukou* reform initiative, the provincial governments would release broad guidelines regarding implementation for their prefectures, and prefectural governments would further decide their provisions on the basis of the national initiative and provincial guidelines.²

To explain the information in these guidelines, consider one example of Hebei Province's guidelines, issued on November 20, 2014 ([Hebei Government, 2014](#)).

[...]

- (II.2) **Fully lift restrictions on settlement in urban areas of prefectures with a population of less than 1 million.** In the urban areas of Chengde, Zhangjiakou, Qinhuangdao, Cangzhou, Hengshui, and Xingtai, where the population is less than 1 million, people who have a legal and stable residence, and their spouses, children, and parents of both spouses who live together, can apply for a local *hukou*.
- (II.3) **Reasonably determine the conditions for settlement in urban areas of prefectures with a population of more than 1 million.** In urban areas of Shijiazhuang, Tangshan, Baoding, and Handan, where the population is more than 1 million, if one of the following conditions is met, the individual and his/her spouse, children, and parents of both spouses living together can apply for a local permanent residence permit:
 - (a) Persons with legal and fixed residences. Legal and fixed residences include self-purchased houses and legally self-built houses (the same below) that meet the living conditions and are actually lived in;
 - (b) Persons with legal and stable occupations and other legal and stable residences. Persons with legal and stable occupations include those

²In principle, the county governments can further specify their own guidelines. However, the prefectural guidelines are already detailed enough, leaving little room for further discretion to be used. Therefore, in practice, we find very few guidelines at the county level.

employed by administrative organs, people's organizations, and institutions or those who have signed labor contracts with enterprises in accordance with the law and have participated in the basic pension insurance for urban employees for a certain number of years; those who have obtained industrial and commercial business licenses in accordance with the law and paid taxes in accordance with the law for a certain number of years; and those who are engaged in freelance occupations and have obtained residence permits for a certain number of years. Other legal and stable residences refer to legal and stable residences other than legal and fixed residences. The specific time limit for participating in the basic pension insurance for urban employees, paying taxes in accordance with the law, and obtaining residence permits shall be determined by the governments of each prefecture-level city in light of local conditions, and in principle shall not exceed 1 year.

As the provincial capital, Shijiazhuang should optimize the personnel structure in the urban area. On the basis of the above conditions, reasonable regulations can be made on the scope of legal and stable occupations and legal and stable residences, and the time limit for participating in the basic pension insurance for urban employees, paying taxes in accordance with the law, and obtaining residence permits according to the actual situation.

- (II.4) **Reasonably determine the settlement conditions in towns around the national capital.** In the urban area of Langfang City, Sanhe City and its subordinate towns, Dachang Hui Autonomous County, Xianghe County, Yongqing County, Gu'an County government seat town, and other towns around the capital, those who have a legal and stable job and a legal and stable residence and have participated in social insurance for a certain number of years in accordance with national regulations, and the person himself and his spouse, children, and parents of both spouses who live together, can apply for a local permanent residence. The scope of legal and stable jobs, legal and stable residences, and the number of years of participation in social insurance shall be specifically stipulated by the Langfang Municipal Government based on actual conditions. No requirements such as area and amount shall be set for legal and stable residences, and the number of years of participation in social insurance shall not exceed 5 years.

[...]

The guidelines provided a broad picture of how the *hukou* reforms would unfold in the prefectures of Hebei. Per (II.2), one can know that Chengde, Zhangjiakou, Zhangjiakou, Qinhuangdao, Cangzhou, Hengshui, and Xingtai are mandated to lift their restrictions on *hukou* transfers, thus, they are coded to be reform prefectures. By contrast, the tone in (II.3) is more subtle for Shijiazhuang, Tangshan, Baoding, and Handan—they have some discretion in deciding their

requirements regarding residence and jobs, but they need to abide by the provincial government's guidelines. Thus, it is necessary to examine the actual provisions made by these prefectural governments to know their reform status. For instance, after review, we find that Shijiazhuang provided lenient requirements although the provincial government specifically allowed it to maintain tight control due to its provincial capital status. Lastly, per (III.3), one can know that Langfang should maintain tight control since it neighbors Beijing.

Generalizing this reading of Hubei Province's reform guidelines, we manually code up each prefecture's actual reform status through the following two-step procedure.

1. A prefecture is coded as "reform" if the provincial guidelines unambiguously mandate it to "fully lift restrictions."
2. If the reform status is not determined at step 1, we obtain and read the prefecture's own guidelines to find out its reform status. We code a prefecture as "non-reform" if it has any restrictive provisions on granting *hukou* transfers as follows:
 - (a) A point-based system to screen migrants;
 - (b) A requirement of having had a long duration of stay in the prefecture or enrollment in the local social security system (> 3 years);
 - (c) A requirement of select types of stable residences and/or jobs, e.g., only home ownership is eligible or a minimum duration of work experience is required.

Otherwise, a prefecture is coded as "reform."

Table D1 shows the release time of each province's guidelines following the national initiative. Most of them were released in late 2014 or the first half of 2015.

Comparing the population-based (≤ 3 million or not) and manually coded reform status, only 17 out of 287 prefectures, or 6 percent of the sampled prefectures, have a disagreement between the two definitions. Table D2 tabulates these disagreements. In Panel A, 9 large-sized prefectures (urban population > 3 million) relaxed their *hukou* transfers, whereas in Panel B, 8 small-sized prefectures (≤ 3 million) did not relax. We do not interpret these disagreements as local governments' deliberate defiance of the national reform initiative, instead, they can be due to discretion based on local conditions. Prefectures in Panel A may make lenient provisions to attract labor. In contrast, prefectures in Panel B may be the hot spots of population inflows. Langfang is adjacent to Beijing and thus is home to many migrants who work in Beijing, thus, it is urged to maintain tight control. The remaining ones are all prefectures in coastal provinces attractive to new migrants. The Guangdong government even explicitly required Zhuhai and Zhongshan, two manufacturing hubs in the Pearl River Delta, to impose strict restrictions on granting local *hukou*.

Guangdong	Shantou	5.720			

Note: This table tabulates prefectures that have a disagreement between population-based and manually-coded definitions of reform status.

E Auxiliary Data

Local Socioeconomic Variables. Our analysis uses various local socioeconomic variables, which provide detailed information on economic growth, demographics, fiscal expenditures, and local governance. We collect them from several sources: China City Statistical Yearbooks, population census tabulations, as well as data other researchers compile from the Chinese government’s releases (Campante et al., 2023; Rogoff and Yang, 2024).

Trade Data. To construct trade shock measures, we use: (i) the prefecture-level export structure measured using the 2010 Chinese customs database, obtained from Campante et al. (2023), and (ii) global export volumes, also from Campante et al. (2023), which are originally from the UN Comtrade database (https://www.cepii.fr/CEPII/en/bdd_modele/bdd_modele_item.asp?id=37).

Officials’ Promotion Prospects. Following Wang et al. (2020), we estimate a local leader’s *ex ante* promotion prospect in a year. We focus on the party secretary, who is the chief leader of a prefecture. The estimated promotion prospect is a flexible function of the age when he starts the term, his official rank in the bureaucratic system, and some individual characteristics, which can be used as a proxy for his career concerns. This hinges on the personnel rule that mandates retirement ages that increase with bureaucratic ranks.³ Specifically, we estimate the following Probit model:

$$\Pr(Promotion_{it} | \cdot) = \Phi [\beta_0 StartAge_{it} + \beta_1 HighRank_{it} + \beta_2 (StartAge_{it} \times HighRank_{it}) + \mathbf{X}'_{it} \delta]. \quad (\text{E1})$$

i indexes prefectures and *t* indexes terms. The unit of analysis is prefecture-by-term. $Promotion_{it}$ is a dummy that equals one if prefecture *i*’s leader is promoted after term *t*. An outcome after a term ends is considered a promotion if the prefectoral party secretary is appointed to a position ranked higher than his previous rank. However, we exclude rank enhancement as promotion if the prefectoral party secretary is placed in an honorary position in the Chinese People’s Political Consultative Conference (CPPCC) or the People’s Congress (PC) at the prefectoral or provincial level, which is commonly regarded as semi-retirement in China since these positions carry no real power. $StartAge_{it}$ is the age when a party secretary starts the term *t* of prefecture *i*. Most prefectoral party secretaries have a prefectoral (*zhengting*) rank, but some have a higher rank: deputy provincial (*fubu*), provincial (*zhengbu*), or even deputy national (*fuguo*). $HighRank_{it}$ is an indicator of the above deputy provincial rank. \mathbf{X}_{it} includes an officials’ characteristics, including indicators for graduate degree indicator and central government experience.

We use biographical data on local officials compiled by Yao et al. (2022) and Jiang (2018). Our data include 2,305 party secretary terms in 337 prefectures between 2000 and 2017. The average start age is 50.8 years old, and 18.3 percent of party secretaries have an above deputy provincial

³The retirement age is 60 for both prefecture level and deputy-province-level leaders and 65 for province-level leaders.

rank. Table E1 reports the estimation results. The first two columns show estimates by a linear probability model (LPM), and Columns (3) and (4) show estimates by a Probit model. The results are consistent with Table 2 in Wang et al. (2020). We use the estimated model in Column (4) to generate the predicted probability of promotion and use that as an index of promotion prospects.

Table E1. Prediction of Promotion Prospects

	Dependent: Promotion			
	(1) LPM	(2) LPM	(3) Probit	(4) Probit
Start age	-0.026*** (0.003)	-0.025*** (0.003)	-0.093*** (0.009)	-0.089*** (0.009)
Deputy province or above	-1.921*** (0.197)	-1.925*** (0.200)	-8.615*** (1.221)	-8.752*** (1.245)

Observations	2,244	2,244	2,244	2,244

Note: This table reports how we constructed the promotion prospect variable following Wang et al. (2020). Officials' characteristics include indicators for graduate degree and central government experience. Robust standard errors are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

GDELT. GDELT, the abbreviation of the Global Database of Events, Language, and Tone, is a commonly used dataset on global events (www.gdeltproject.org), especially on social unrest (Cantoni et al., 2023). GDELT has conducted automated scraping of the world's broadcast, print, and web news since 1979, and uses machine learning methods to code an event's types, participants, date, location, etc. Given GDELT's wide coverage, we use it to measure the degree of media attention or reporting of local events.

Migrant Survey. We use a nationally representative survey on migrants—China Migrants Dynamic Survey (CMDS hereafter)—conducted annually by China's National Health Commission since 2009, targeting migrants living and working in more than 300 prefectures in 31 provinces across the country. CMDS employs a stratified probability-proportional-to-size sampling method so that the sample size is proportional to the number of migrants in each region. The data provide rich information on migrants' demographics, families, labor market outcomes, and attitudes. CMDS

has a much larger sample size of migrants, ranging from 100 to 200 thousand for each year, than any other survey data in China. We use eight waves of surveys between 2011 and 2018. We focus our attention on individuals of the working ages, 25–54. We only keep individuals in prefectures that appear in all eight waves; as such, our sample covers 255 prefectures.

Population Census Microfile. To study how the *hukou* reform influences migrants' re-migration decisions, we use the microfile of the 2015 mini population census that surveys 1 percent population. The survey was conducted in November 2015. The census asks an individual to retrospect residential locations as of November 2010 and November 2014. Thus we can construct the residential history at three time points: (the end of) 2010, 2014, and 2015. We also observe one's *hukou* registration location in 2015—for those whose *hukou* registration did not change between 2010 and 2015, we can use this information to define migration status back to 2010.

Cultural Distance. Following [Guarnieri \(2025\)](#), we measure cultural distance by linguistic distance. Linguistic data are from *The Language Atlas of China* ([Lavely and Berman, 2012](#)). We treat the smallest category in *The Atlas* as a language. We take a three-step procedure to construct the linguistic distance.

First, we calculate the cladistic distance between two languages x and y ([Fearon and Laitin, 2003](#)):

$$d_{xy} = 1 - \left(\frac{\# \text{ of common nodes between } x \text{ and } y}{\frac{1}{2} \times (\# \text{ of nodes of } x + \# \text{ of nodes of } y)} \right)^{\frac{1}{2}}. \quad (\text{E2})$$

This measure captures the degree to which two languages overlap in the origins. For instance, consider two variants of Mandarin, *Jingshi* (x) and *Huaicheng* (y). Their origin trees are:

x : Sino-Tibetan Phylum → Sinitic Stock → Mandarin supergroup → Beijing Mandarin → *Jingshi*,
 y : Sino-Tibetan Phylum → Sinitic Stock → Mandarin supergroup → Beijing Mandarin → *Huaicheng*.

Then,

$$d_{\text{Jingshi}, \text{Huaicheng}} = 1 - \sqrt{\frac{4}{0.5 \times (5 + 5)}} = 0.106. \quad (\text{E3})$$

If two languages originating from two distinct families have a maximal distance 1.

Second, we calculate the language distance between two prefectures h and i :

$$LD_{hi} = \sum_x \sum_y w_{xh} w_{yi} d_{xy}, \quad (\text{E4})$$

where w_{xh} is the share of population primarily speaking language x in prefecture h , and w_{yi} is similarly defined. *The Atlas* reports the primary spoken in each county, thus, we can calculate weights w 's using population counts from the 2010 census.

Finally, we calculate the average migrant's linguistic distance in prefecture i :

$$L_i^M = \sum_h s_{h \rightarrow i} L_{hi}, \quad (\text{E5})$$

where $s_{h \rightarrow i}$ is the share of migrants from prefecture h to prefecture i , relative to all migrants in prefecture i .

F Other Population-Based Policies

Our estimates for the effects of the *hukou* reform would be contaminated, if there exist other concurrent policies that (i) have provisions correlated with urban population and (ii) can influence labor unrest. To examine this possibility, we conduct a comprehensive search of population-related policies using the *PKULaw* database (<https://www.pkulaw.com>), which provides extensive information on Chinese laws and regulations. It has been used in research on policy-making in China (e.g., [Tian, 2024](#); [Wang and Yang, 2025](#)). We use two keywords to search for urban population-related policies: “urban population (城区人口 in Chinese)” and “city size (城市规模 in Chinese).” The *PKULaw* database has a fuzzy search feature and it would return policies that contain the search keyword and its synonyms. We focus on policies published by the central government, which have the potential of creating provisions tiered by urban population.

Results of Searches Based on “Urban Population.” We first use the keyword “urban population.” Table F1 tabulates the number of policies published by the central government. Overall, *PKULaw* returns a total of 126 relevant policies during 2011–2019. We take a closer look at these policies. The *PKULaw* database classifies the policies into 9 domains. The “regional planning” domain accounts for the largest share of policies mentioning “urban population.” It includes: (i) the central government’s approvals of specific regions’ development plans, and (ii) the central government’s own development plans for particular regions. In these policies, “urban population” or synonyms are mentioned to describe the population status of a region, rather than systematically specifying provisions tiered by urban population. For example, in the State Council’s approval of the Fuzhou Prefecture’s urban development plan in 2015,⁴ it was stated:

“By 2020, the permanent population in the central urban area will be controlled within 4.1 million people, and the urban construction land will be controlled within 378 square kilometers.”

The 2014 *hukou* reform falls in the domain of “government work.” The other policy in 2014 in the “government tasks” domain was a general proposal regarding the development of regions near the Yangtze River.⁵ The policy of this domain in 2017 was to divide tasks between branches within the central government.⁶ Both policies did not outline provisions that vary by urban population.

⁴https://www.gov.cn/gongbao/content/2015/content_2912363.htm

⁵State Council’s Notice on Relying on Golden Waterways Guidance on promoting the development of the Yangtze River Economic Belt (https://www.gov.cn/zhengce/content/2014-09/25/content_9092.htm).

⁶State Council’s Opinions on the Implementation of the Government Work Report: The Division of labor among departments (https://www.gov.cn/zhengce/content/2017-03/28/content_5181530.htm).

The policy of the “labor unions” domain may be worth noting. However, it called labor unions to facilitate increasing employment and had no provisions based on urban population tiers.⁷ Thus, again, it would not be a confounding policy for the purpose of our paper.

Among all these policies during the period under study, we identify six policies as population-based policies, which are listed as follows:

1. **Opinions of the State Council on Further Promoting the Reform of the Household Registration System in 2014.**⁸ The detail of this policy is described in Section 2.1.
2. **Opinions of the State Council on Promoting the Development of Prefabricated Construction in 2016.**⁹ The document states that cities with population over 3 million are regions for active promotion of the prefabricated construction development, while other cities are considered regions for encouraged promotion.
3. **Notice of the State Council on Issuing the Ecological and Environmental Protection Plan for the 13th Five-Year Plan (2016).**¹⁰ “By 2020, public transportation in built-up areas of cities with a permanent population of more than 3 million will account for 60% of motorized travel.”
4. **Notice of the State Council on Issuing the 13th Five-Year Plan for the Development of a Modern Comprehensive Transportation System in 2017.**¹¹ This document states that by 2020 high-speed rail should cover more than 80% of the cities with an urban population over 1 million, while railways, highways, and civil aviation airports should basically cover cities with urban population over 0.2 million.
5. **Opinions of the State Council on Further Strengthening the Planning and Management of Urban Rail Transit Construction in 2018.**¹² This document makes the strict requirement that cities applying to build a metro system should generally have a public fiscal budget of more than 30 billion yuan, a regional GDP of over 300 billion yuan, and an urban population of over 3 million.
6. **Opinions of the State Council on Promoting the Improvement and Expansion of the Domestic Service Industry in 2019.**¹³ The document brings that cities with urban population over 1 million should achieve full coverage of domestic service training capabilities by 2022.

Aside from the *hukou* policy, only the 2016 policy on the development of prefabricated construction uses the 3 million population threshold. Since this policy focuses on altering the construction process by separating material production from assembly, it is not very concerning to our analysis

⁷Notice of the State Council on Issuing the Employment Promotion Plan for the 13th Five-Year Plan (https://www.gov.cn/zhengce/content/2017-02/06/content_5165797.htm).

⁸https://www.gov.cn/zhengce/content/2014-07/30/content_8944.htm.

⁹https://www.gov.cn/zhengce/content/2016-09/30/content_5114118.htm.

¹⁰https://www.gov.cn/zhengce/content/2016-12/05/content_5143290.htm

¹¹https://www.gov.cn/zhengce/content/2017-02/28/content_5171345.htm.

¹²https://www.gov.cn/zhengce/content/2018-07/13/content_5306202.htm.

¹³https://www.gov.cn/zhengce/content/2019-06/26/content_5403340.htm.

of the *hukou* reform. The domains of other policies are also not likely to have first-order impacts on labor unrest.

Results of Searches Based on “City Size.” Table F2 tabulates the number of policies containing the keyword “city size” or terms with similar meanings by year and policy domain. Similar to the results using keyword “urban population,” most policies containing the keyword “city size” or its synonyms fall into the “regional planning” domain, where the word “city size” is used to describe the city status. Among all the other policies, we identify one policy with provisions tiered by urban population.

- Opinions of the State Council on Accelerating the Promotion of Ecological Civilization Construction in 2015.¹⁴** The document proposes to base urban planning on the carrying capacity of resources and the environment, strictly control the size of mega-cities, and enhance the capacity of small and medium-sized cities.

Due to its environmental focus, we do not believe it can have a first-order impact on labor unrest.

Table F1. Search Results Using Keyword “Urban Population”

Year	Regional Planning	Government Tasks	Resources & Environment	Labor Union	Transport	Science & Education	Health	Others	Total
2011	15	0	1	0	0	0	0	1	17
2012	28	0	0	0	0	0	0	4	32
2013	7	0	1	0	0	0	1	3	12

Note: This table summarizes the count of policies containing the keyword “city size” or terms with similar meanings by year and policy domain.

G Supplementary Results for Main Findings

G.1 Robustness to Sampling of Prefectures

The main sample includes 287 prefectures that urban population in 2014 is available (from the Urban Construction Statistical Yearbook). We show that our results are not driven by this sampling decision. Specifically, we present results based on three alternative samples:

1. 287 prefectures in the main sample and prefectures in Tibet and Xinjiang that urban population in 2014 is available (in total, 298 prefectures);
2. All prefectures that urban population in 2014 is available (in total, 303 prefectures);
3. All prefectures in China (in total, 337 prefectures).

For each sample, we report both the DiD and DiDC estimates. One thing to note is, when using the sample of all 337 prefectures, some 34 of them do not have urban population in 2014 available. To include them in estimation, we define their reform status as reform, i.e., $Reform_i = 1$, as they are presumably small. This is confirmed by the 2010 population census: all of them had an urban population below 3 million in 2010 (maximum = 1.597 million). To implement the DiDC estimation, we also calculate the 34 prefectures' running variable \tilde{p}_i using urban population in 2010 as reported by the 2010 population census.

Table G1 reports the results. Clearly, no matter which sample is used, the results consistently imply that the *hukou* reform reduced labor unrest. The effect size does not vary markedly by sample used. Figure G1 displays the event-study estimates based on different samples. Again, the negative effect of *hukou* reform on labor unrest is not due to a particular sampling choice.

G.2 Sensitivity Test for Potential Violations of Local Parallel Trends

This section follows [Fenizia and Saggio \(2024\)](#) and [Rambachan and Roth \(2023\)](#) to address potential concerns about violations of *local* parallel trends (for prefectures around the reform cutoff).

First, we can fit a linear trend based on the pre-reform event study estimates and extrapolate it to the post-reform periods, as shown by the first column of Figure G2. Apparently, the pretrends are slightly upward. If these trends persist to the post-reform periods, the decline in unrest rates indicated by the post-reform event study estimates would in fact *underestimate* the true effects. We can correct this bias for these estimates by calculating their deviations from the extrapolated linear trend. The middle column of Figure G2 reports these detrended event study results. They confirm that the *hukou* reform has significantly negative effects on unrest rates.

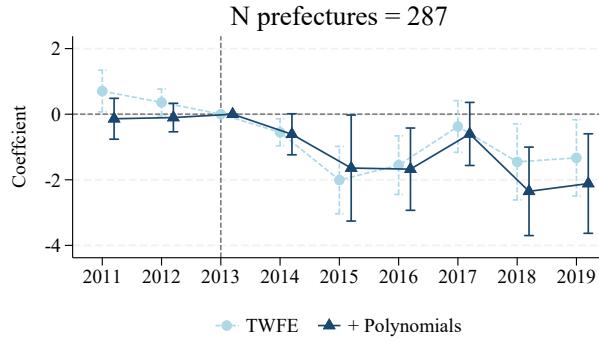

In the last column of Figure G2, we use the methodology developed by [Rambachan and Roth \(2023\)](#) to evaluate the sensitivity of our results to violations of local parallel trends. This approach

Table G1. Robustness to Sampling of Prefectures

	Main sample		Plus Tibet & Xinjiang		Urban population available		All prefectures	
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
	Unrest/L	Unrest/L	Unrest/L	Unrest/L	Unrest/L	Unrest/L	Unrest/L	Unrest/L
Reform × Post	-1.567*** (0.271)	-1.419*** (0.373)	-1.551*** (0.271)	-1.214*** (0.375)	-1.578*** (0.270)	-1.124*** (0.370)	-1.661*** (0.269)	-1.201*** (0.360)
Control mean	3.395	3.395	3.335	3.335	3.335	3.335	3.335	3.335
Prefecture FE	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Polynomials		Yes		Yes		Yes		Yes [†]
No. prefectures	287	287	298	298	303	303	337	337
Observations	2,583	2,583	2,682	2,682	2,727	2,727	3,033	3,033

Note: This table presents the robustness of our results to the sampling of prefectures. Columns (1)-(2) display results based on the main sample of 287 prefectures, which are the same as Columns (1)-(2) in Table 3. Columns (3)-(4) use a sample that includes prefectures in Tibet and Xinjiang (whose urban population in 2014 is available). Columns (5)-(6) use the sample of all prefectures whose urban population in 2014 is available. Columns (7)-(8) use all 337 prefectures. In these regressions, the prefectures whose urban population in 2014 is not available are defined as reform prefectures, as they are presumably small and have an urban population below 3 million. Their \bar{p}_i is calculated based on urban population from the 2010 census. Standard errors clustered at the prefecture level are reported in parentheses.
* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

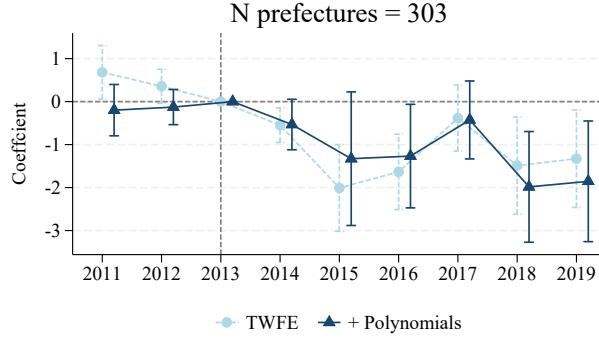

A. Main Sample

B. Tibet and Xinjiang Included

C. All with Urban Population Available

D. All Prefectures

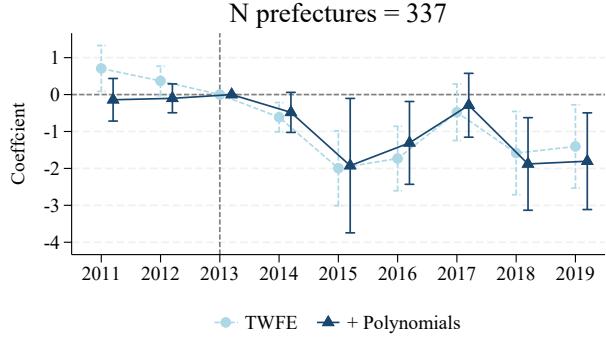

Figure G1. Robustness to Sampling of Prefectures: Event Study

allows more nonlinear differential trends. Specifically, it imposes the following condition to the change in the slope of the differential trend between reform and non-reform prefectures between

two consecutive periods:

$$|(\theta_{t+1} - \theta_t) - (\theta_t - \theta_{t-1})| \leq M. \quad (\text{G1})$$

θ_t is the slope of the differential trend in period t . M governs the range of slope changes, namely, the degree of non-linearity of the differential trend. $M = 0$ corresponds to a linear differential trend. A larger M thus allows a more nonlinear differential trend. For every given M , the method then tests the null, conditional on the possible differential trend, whether the *hukou* reform has a significant effect on unrest—defined as the average of post-reform event study coefficients. Figure G2 shows that our results can withstand very nonlinear differential trends. For instance, consider Figure G2C that reports the sensitivity test for the event study using the full sample, we can reject a null effect up to when M is 0.03. Compared to the slope of the linear trend implied by pre-reform event study coefficients, 0.076, this means that the differential trend's slope must change by more than $\pm \frac{0.03}{0.076} \approx \pm 39.4\%$ of the slope the linear extrapolation in each period. In other words, only when a very wiggly differential trend is imposed should we not reject a null effect. Likewise, the narrow sample results can also tolerate a high degree of non-linearity in differential trends. Figure G2C suggests that we cannot reject a null effect only if we are willing to assume that the differential trend's slope is more than $\pm \frac{0.06}{0.311} \approx \pm 19.3\%$ off the linear pre-trend slope.

Taken together, we show our results are robust to allowing a linear differential trend implied by the pretrends. In addition, the results hold even if there is a significant amount of non-linearity in differential trends.

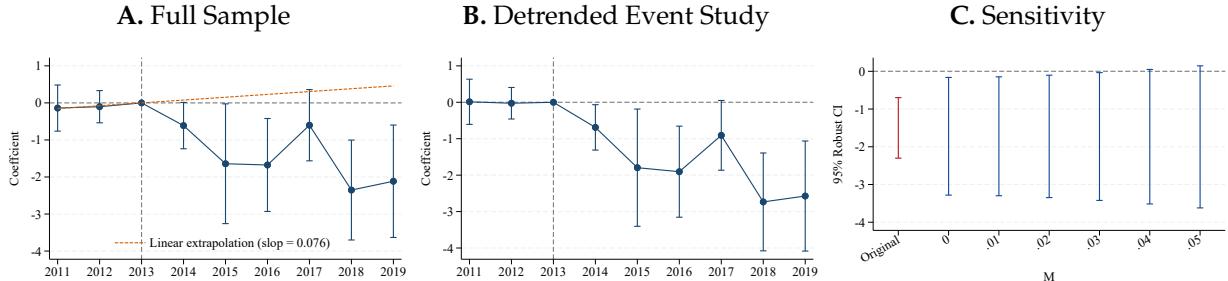

Figure G2. Detrended Event-Study Coefficients and Application of Rambachan and Roth (2023)

Note: This figure reports the sensitivity test for the event study results. The first column depicts the linear trend implied by pre-reform event study coefficients and it is extrapolated to post-reform periods. The middle column shows the deviations of event study coefficients from the linear trend. The last column reports the results of applying the methodology developed by Rambachan and Roth (2023), which tests whether the average of post-reform coefficients are statistically distinguishable from zero given different levels of non-linearity in potential differential trends (governed by M).

G.3 Robustness to Choices of Bandwidths, Kernels, and Polynomial Orders

Bandwidths. Figure G3 presents the estimated coefficient on $Reform_i \times Post_t$ in Equation 2, when we impose different bandwidth restrictions to our sample. We note three commonly used optimal bandwidths proposed in the literature: Calonico et al. (2014) a.k.a. CCT, Imbens and Kalyanaraman (2012) a.k.a. IK, and cross validation a.k.a. CV. The estimates are overall stable across different

bandwidth choices. Note that when the bandwidth falls below the IK optimal bandwidth, the estimates become much noisier due to the small sample size. Thus, we opt to use the IK optimal bandwidth for our narrow sample.

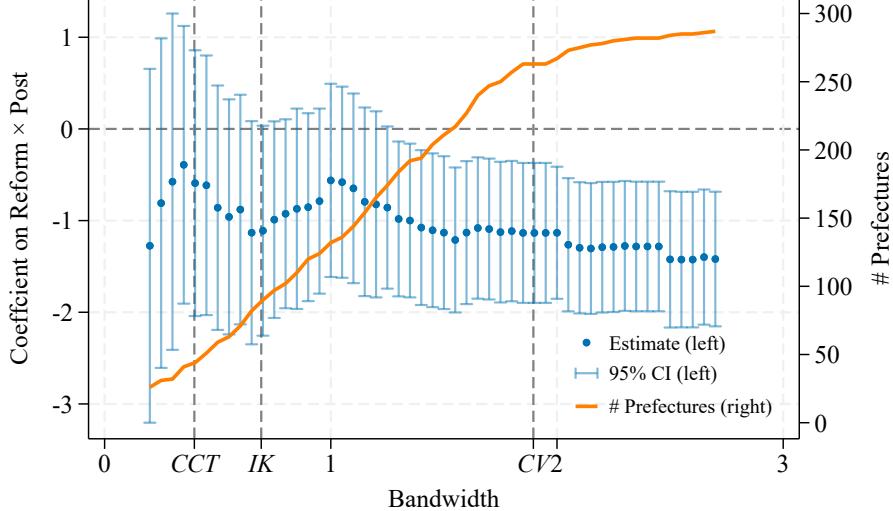

Figure G3. Estimates under Different Bandwidth Choices

Note: This figure presents the estimated coefficient on $Reform_i \times Post_t$ in Equation 2, when we impose different bandwidth restrictions to our sample. We note three commonly used optimal bandwidths proposed in the literature: Calonico et al. (2014) a.k.a. CCT, Imbens and Kalyanaraman (2012) a.k.a. IK, and cross validation a.k.a. CV. Standard errors clustered at the prefecture level are used to construct the 95 percent confidence intervals.

Kernels. Our baseline results place equal weights on prefectures, i.e., the uniform kernel is used. We examine the robustness to choices of kernels. We consider two alternative kernels common in the literature: triangular and Epanechnikov kernels, which place high weights on prefectures closer to the cutoff $\tilde{p}_i = 0$. Using these two kernels, we then re-estimate Equation 2. Figure G4 shows that using alternative kernels yields similar estimates of β in Equation 2 as in the baseline.

Polynomial Orders. Figure G5 presents event-study results for the effects of the *hukou* reform on labor unrest using quadratic and cubic polynomials of \tilde{p}_i . Compared to the baseline results that use linear polynomials in Figure 2, these results are noisier, likely due to over-fitting with the introduction of higher-order polynomials (Gelman and Imbens, 2019). Nonetheless, it is clear that after the *hukou* reform became in effect, labor unrest rates in reform prefectures decreased relatively.

G.4 Reporting of Local Events

General Coverage of Local Events. Given that CLB data rely on online reports about labor unrest, we investigate if the *hukou* reform affects reporting of local events so that we observe a decrease in unrest rates in reform prefectures. We make use of the Global Database of Events, Language, and Tone Project (GDELT). It records events based on articles from a comprehensive, global set of

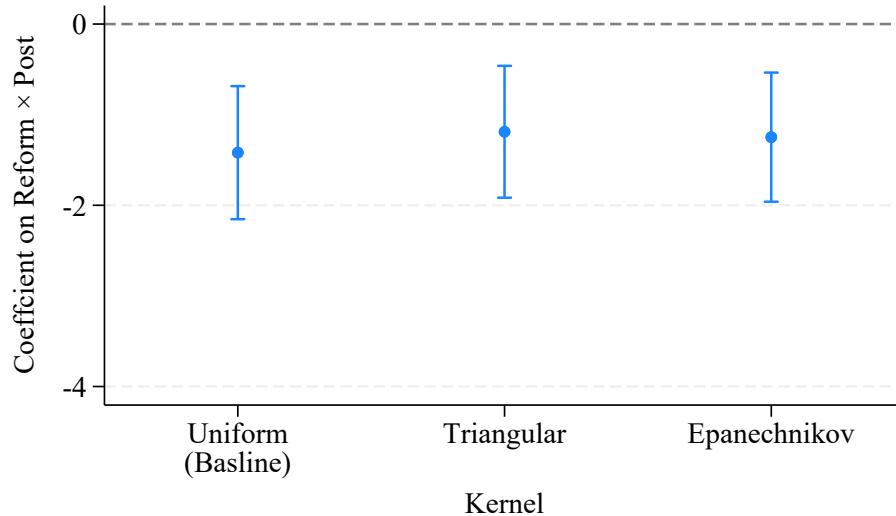

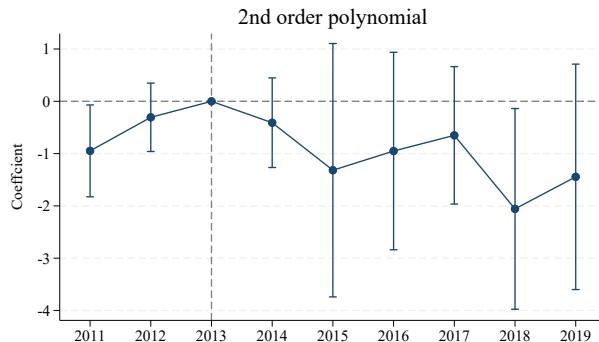

Figure G4. Robustness to Kernel Choices

Note: This table presents the robustness to kernel choices. We estimate Equation 2 using three kernels: uniform kernel (baseline), triangular kernel, and Epanechnikov kernel. The solid dots denote the point estimates of β in Equation 2. The caps are 95 percent confidence intervals. Standard errors are clustered at the prefecture level.

A. 2nd Order Polynomials

B. 3rd Order Polynomials

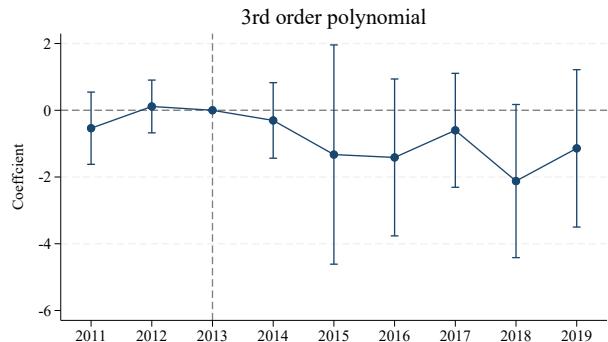

Figure G5. Robustness to Alternative Polynomial Orders

Note: This figure presents the event study results using polynomial orders. The solid dots are point estimates, and the caps are 95 percent confidence intervals. Standard errors clustered at the prefecture level are used to construct confidence intervals.

news feeds, and it also uses automated textual analysis to extract characteristics of recorded events, such as date, location, type of the event, parties involved, etc. Thus, we use the number of events recorded by GDELT (scaled by working-age population) as a measure of coverage of local events, the variation of which can be due to either media attention or information outflows. Column (1) of Table G2 shows that there are no significant differential trends in the number of events reported between reform and non-reform prefectures. If anything, reform prefectures experienced

an increase in coverage. Column (2) looks at the reporting of protest events.¹⁵ Likewise, we do not find the reporting of protests varies significantly by reform status.

Internet Censorship. Internet censorship was rising during the period we study (King et al., 2017). One may be concerned that reform prefectures' decrease in unrest rates is an artifact of changes in reporting of local events due to censorship. To rule out this concern, we measure censorship as the share of deleted Weibo posts in the prefecture's affiliated province using data from Qin et al. (2017),¹⁶ and control the interaction term of censorship level and the year fixed effect. Column (3) shows that the effect of the reform persists after incorporating the time-variant impact of censorship.

Self-Censorship. If workers in reform prefectures became less likely to report their actions online than their counterparts in non-reform prefectures after the reform, then we would observe a mechanical decrease in labor unrest rates in reform prefectures. To examine the role of self-censorship, we consider the most influential scenario for self-censorship to drive our results. When post-reform self-censorship rose primarily in reform prefectures that reported high unrest rates before the reform, we are more likely to obtain an artificial, negative effect of the *hukou* reform on labor unrest rates. If the dynamics of self-censorship play a major role in our findings, then excluding reform prefectures with high reported pre-reform unrest rates would attenuate the estimated effect of the *hukou* reform on labor unrest.

In light of this idea, within reform prefectures, we exclude reform prefectures with high pre-reform unrest rates in the top X -th percentile (X is varied), and re-estimate Equation 2 using the sample with some reform prefectures excluded (depending on X). However, as shown by Figure G6, the estimated effect remains stable when excluding reform prefectures with reported high pre-reform unrest rates, indicating a limited role of self-censorship in explaining our results.

In conclusion, the negative effect of the *hukou* reform on labor unrest is not likely due to variation in reporting of local events.

G.5 The Effects of the *Hukou* Reform on Population

In this section, we investigate the effects of the *hukou* reform on total population, urban population, and native urban population (urban residents with local *hukou*). We study the effects on both levels and growth rates. Figure G7 reports event study estimates using the DiDC strategy. For completeness, we also report estimates using the DiD strategy. Regarding total population, the DiD estimates in Figure G7A show that reform prefectures exhibit a downward linear trend in total

¹⁵The type of an event is identified by the Conflict and Mediation Event Observations (CAMEO) code using machine learning. Column (2) restricts analysis to events with CAMEO code "14: Protest", which includes a range of protest activities including demonstrations, rallies, strikes, and violent protests.

¹⁶Qin et al. (2017) measure the level of censorship using the share of deleted posts on Weibo at the provincial level in 2013.

Table G2. *Hukou* Reform and Reporting of Local Events

	(1) All events/L GDELT	(2) Protests/L GDELT	(3) Unrest/L CLB
Reform × Post	758.064 (642.532)	9.086 (6.801)	-1.207*** (0.362)
Control mean	722.131	6.573	3.416
Prefecture FE	Yes	Yes	Yes
Year FE	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes
Censorship level × Year FE			Yes
Observations	4,420	4,420	2,331

Note: The dependent variables in Columns (1) and (2) are the number of local events and the number of protests recorded in GDELT (scaled by working-age population). The dependent variable in Column (3) is the number of labor unrest events in CLB data with the same scaling. “Censorship level” is the share of deleted Weibo posts in a prefecture’s affiliated province, based on data from Qin et al. (2017). Robust standard errors are clustered at the prefecture level and reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

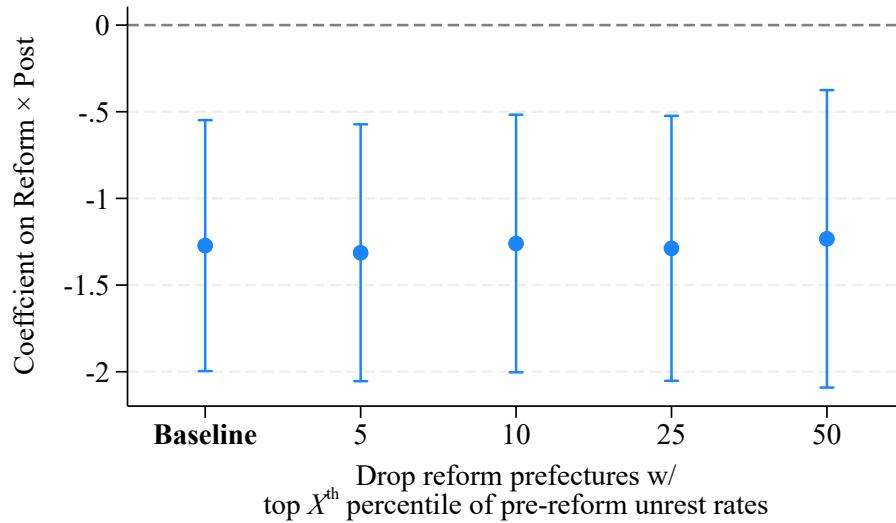

Figure G6. Addressing the Alternative Interpretation of Increased Self-Censorship

Note: This table examines the extent to which the results are driven by differential trends in self-censorship. Within reform prefectures, we exclude those with high *pre-reform* unrest rates in the top X -th percentile (X is varied). We estimate Equation 2 using the sample with some reform prefectures excluded (depending on X). The solid dots in the figure are the point estimates of β . The caps are 95 percent confidence intervals. Standard errors are clustered at the prefecture level.

population (in log), and the growth rate does not vary significantly over time (see Figure G7B); by flexibly controlling for heterogeneity due to urban sizes, the DiDC estimates show that despite moderate pretrends, there appears to be a relative decline in total population after the reform starts, which is due to a drop in population growth rate. These results indicate the *hukou* reform has a

null effect or possibly a negative effect on a prefecture's total population. When it comes to urban population and native urban population, both DiD and DiDC estimates indicate null effects.

In sum, these results suggest that the *hukou* reform has no discernible effects on both total and urban population. If anything, there may be a negative effect on total population.

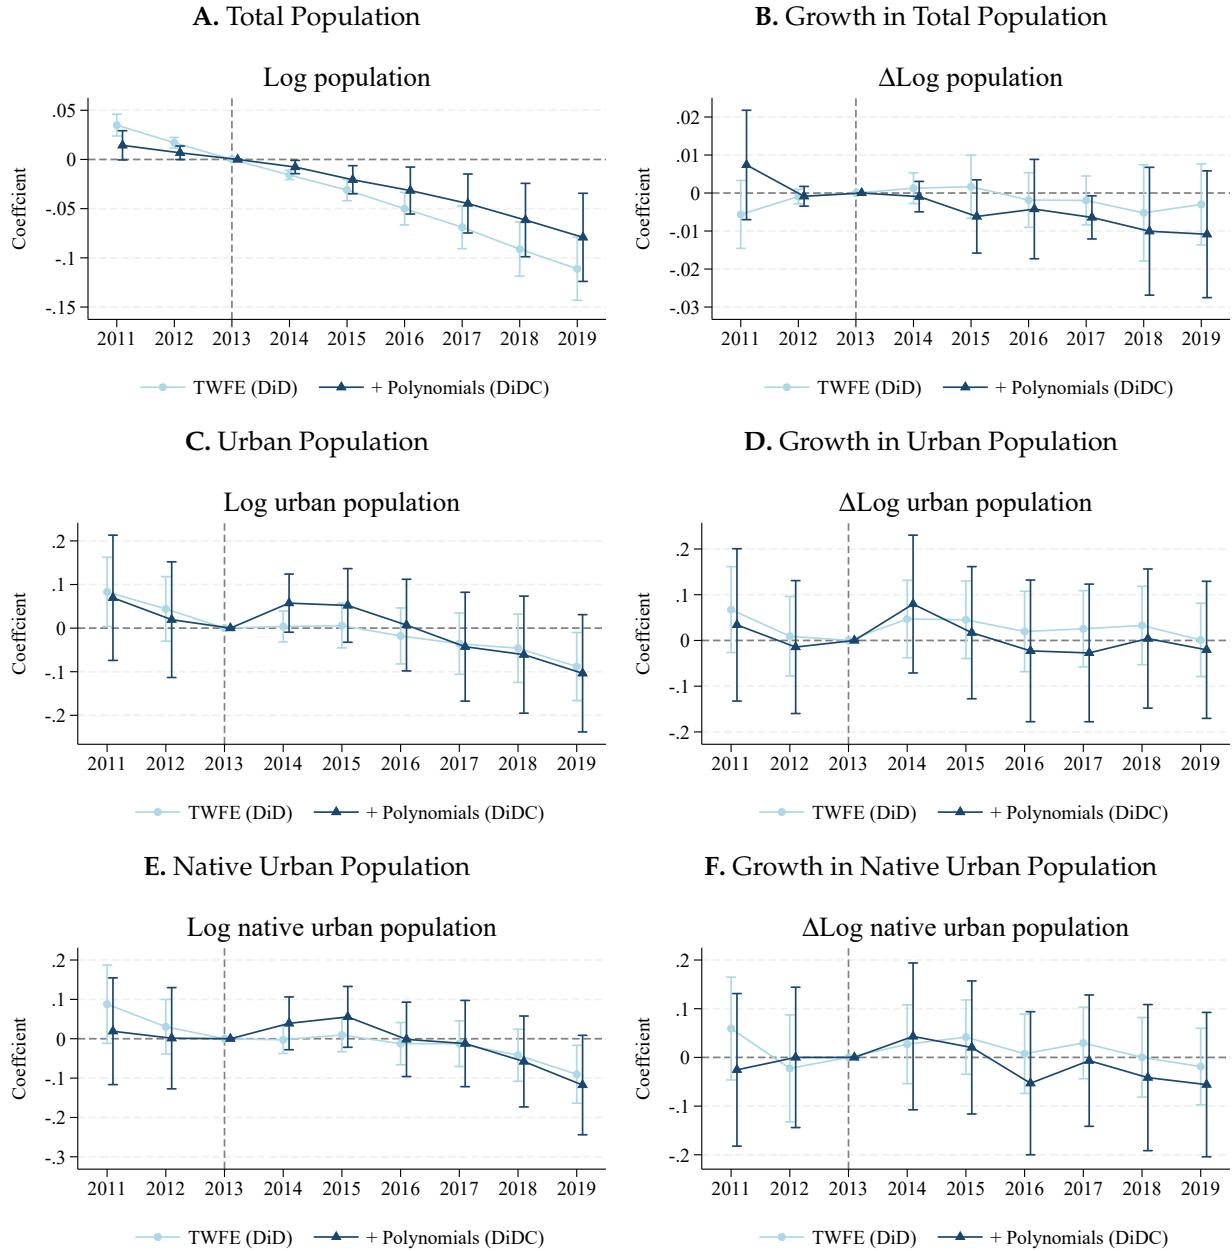

Figure G7. Dynamic Effects of the *Hukou* Reform on Population

Note: This figure reports the dynamic effects of the *hukou* reform on total population, urban population, and native urban population (urban residents with local *hukou*). We look at both their levels (in log points) and growth rates. We estimate event study models modified respectively from Equations 1 and 2. The solid dots are point estimates, and the caps are 95 percent confidence intervals. Standard errors clustered at the prefecture level are used for constructing confidence intervals.

G.6 Addressing Time-Varying Prefecture Sizes

For our main results reported in Section 4, we scale the number of labor unrest events using working-age population, measured in the population census of 2010. One concern is that the results are simply due to time varying prefectures sizes rather than changes in underlying engagement of unrest. We show that our results hold even if we use time-varying population for scaling. There are no annual data on working population. Instead, we use time-varying total population and urban population, sourced from [Rogoff and Yang \(2024\)](#) and the Urban Construction Statistical Yearbooks, respectively. Figure G8 reports the results, confirming our findings that the *hukou* reform leads to a significant decrease in unrest rates.

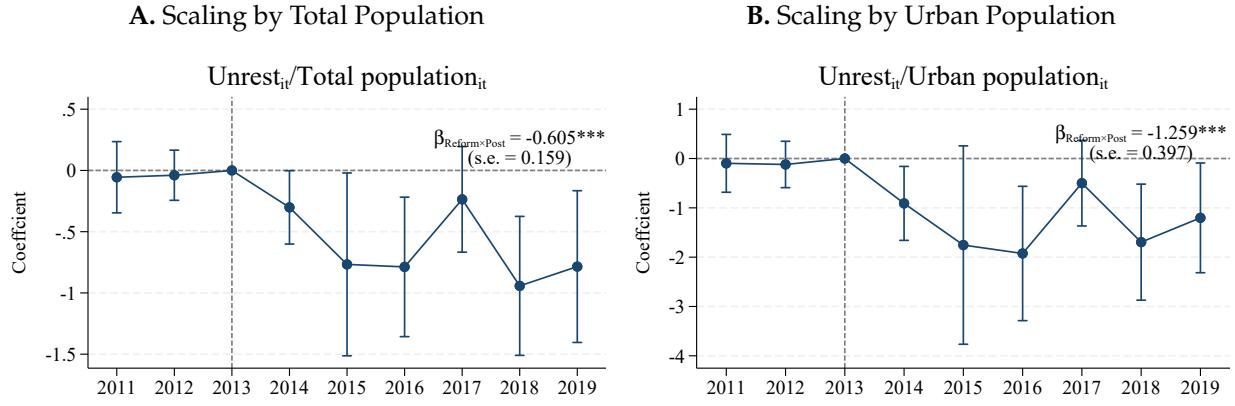

Figure G8. Scaling Unrest Events Using Time-Varying Prefecture Size

Note: This figure reports the results when the number of unrest events is scaled by time-varying population size. Figure G8A uses total population, and Figure G8B uses urban population. We visualize estimates from a dynamic specification: $Y_{it} = \sum_{s \neq 2013} \beta_s (Reform_i \times D_s) + f(\tilde{p}_{i,2014}; \zeta_{Reform,t}) + \lambda_i + \mu_t + \varepsilon_{it}$. The solid points are points estimates of β_s 's, and the caps are 95 percent confidence intervals. We also report the estimate from a static specification: $Y_{it} = \beta (Reform_i \times Post_t) + f(\tilde{p}_{i,2014}; \zeta_{Reform,t}) + \lambda_i + \mu_t + \varepsilon_{it}$. All standard errors are clustered at the prefecture level.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

H Additional Robustness Checks

H.1 Alternative Standard Errors

Table H1 shows that our results are robust to different standard errors. To ease comparison, Column (1) presents results with standard errors clustered at the prefecture level. In Column (2), standard errors are clustered at the province level. As there are only 29 provinces, to deal with invalid asymptotics due to the small number of clusters, we follow Cameron et al. (2008) and implement a wild bootstrap-*t* procedure to compute the *p*-value. In Columns (3) and (4), we use Conley standard errors to address the spatial correlations in error terms (Conley, 1999): we assume that the error terms are serially correlated and spatially correlated between observations within a certain distance (300km or 500km). All the results confirm the statistical significance of our results.

Table H1. Robustness: Alternative Standard Errors

	(1)	(2)	(3)	(4)
	Unrest/L	Unrest/L	Unrest/L	Unrest/L
Reform × Post	-1.419*** (0.373)	-1.419*** (0.399)	-1.419*** (0.332)	-1.419*** (0.335)
SE type	Clustered by prefecture	Clustered by province	Conley, 300km	Conley, 500km
Wild-bootstrap <i>p</i> -value		0.002		
Observations	2,583	2,583	2,583	2,583

Note: This table examines the robustness to alternative standard errors. Column (1) presents results with standard errors clustered at the prefecture level. Column (2) uses standard errors clustered at the province level, and *p*-value is computed through a wild bootstrap-*t* procedure (Cameron et al., 2008). Columns (3) and (4) use Conley standard errors (Conley, 1999).

* *p* < 0.1 ** *p* < 0.05 *** *p* < 0.01

H.2 Alternative Specifications and Estimators

We show that our results are robust to using alternative specifications and estimators. First, instead of the linear polynomial function, we use quadratic and cubic polynomial functions. Second, we use alternative forms of unrest rate $\frac{Unrest_{it}}{L_{i,2010}}$. We take the log of the unrest rate (plus one) or use the inverse hyperbolic sine (IHS) transformation. Third, due to the count data nature, we use the pseudo Poisson maximum likelihood estimation. Fourth, we estimate a spatial autoregressive model to take into account potential spatial spillovers.

The results using these methods are reported in Table H2. We also report the event study estimates in Figure H1. All results confirm that the *hukou* reform significantly reduces unrest rates.

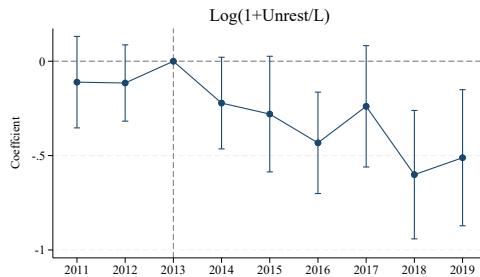

Table H2. Robustness: Alternative Specifications and Estimators

	Alt. Unrest Measures		PPML	SAR
	(1)	(2)	(3)	(4)
	Log(Unrest/L)	IHS(Unrest/L)	Unrest/L	Unrest/L
Reform × Post	-0.305*** (0.086)	-0.383*** (0.112)	-0.545* (0.308)	-1.456*** (0.363)
Control mean	1.209	1.549	3.395	3.395
Method	OLS	OLS	PPML	SAR

Year FE	Yes	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes	Yes
Observations	2,583	2,583	2,583	2,583

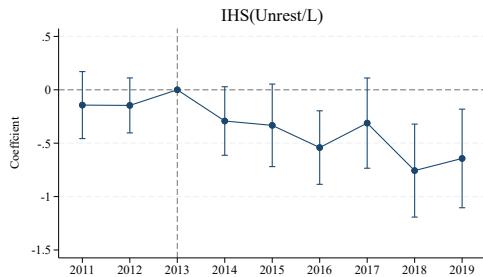

Note: This table examines the robustness to alternative specifications and estimators. Column (1) takes the log of unrest rate (plus one). Column (2) takes the inverse hyperbolic sine (IHS) transformation. Column (3) implements pseudo Poisson maximum likelihood (PPML) estimation. Column (4) estimates a spatial autoregressive (SAR) model. Standard errors are clustered at the prefecture level and reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

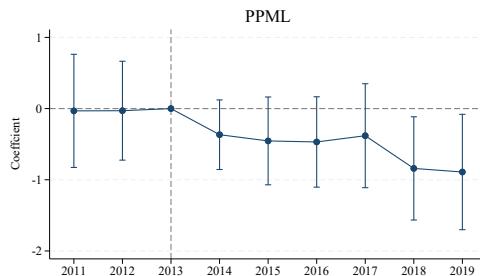

A. Log Transformation

B. IHS Transformation

C. PPML

D. SAR

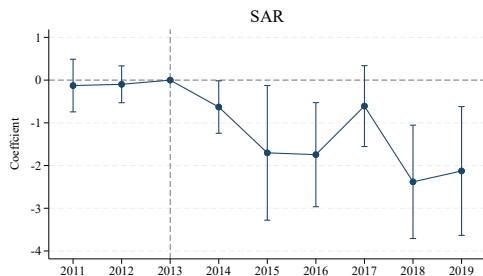

Figure H1. Robustness: Alternative Specifications and Estimators, Event-Study Results

Note: This figure presents the event study results using alternative specifications and estimators. The solid dots are point estimates, and the caps are 95 percent confidence intervals. Standard errors clustered at the prefecture level are used to construct confidence intervals.

H.3 Addressing Potential Outliers

To investigate if there are any special regional factors driving our results, we exclude one province each time and re-estimate Equation 2. Figure H2 shows the estimated coefficients on $Reform_i \times Post_t$. Compared to the baseline estimate using the entire sample, dropping any province has no marked influence. We consistently find a negative effect of the *hukou* reform on unrest rates.

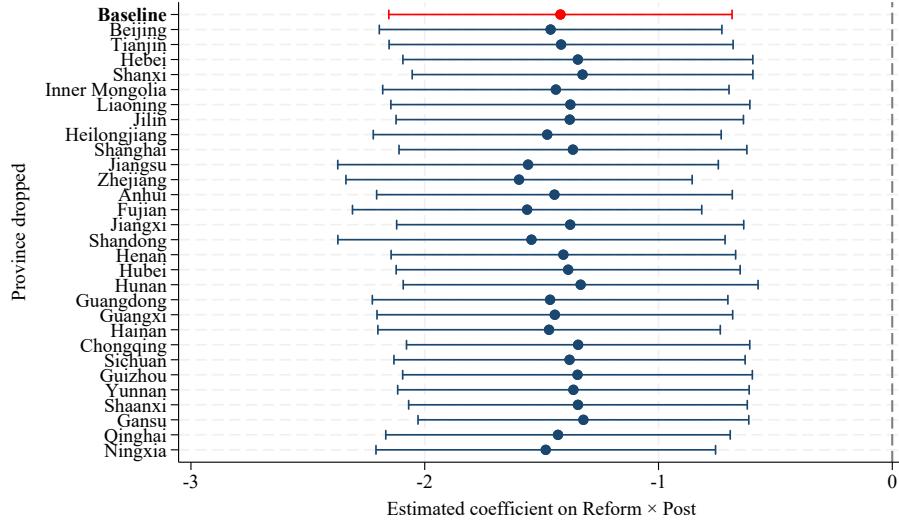

Figure H2. Robustness: Dropping One Province Each Time

Note: This figure reports the estimated coefficient on $Reform_i \times Post_t$ from Equation 2, using the entire sample less one province. For comparison, we also present the baseline estimated coefficient using the entire sample (in red). The solid points are point estimates, and the caps are 95 percent confidence intervals. Standard errors are clustered at the prefecture level.

In Table H3, we show our results are not driven by other potential outlier observations. In Column (1), we exclude prefectures that never had unrest events recorded in the CLB data. However, there was only one such prefecture. In Column (2), in the spirit of donut hole RD that aims to address likely sorting around the cutoff, we remove prefectures that have urban population size very close to the reform cutoff, specifically, $|\tilde{p}_i| < 0.2$. In Column (3), we exclude prefectures whose population-based reform status does not agree with manually coded reform status, for the concern that these prefectures do not “comply” due to unrest considerations. But recall from Section 3.1, we only have 17 prefectures with such discrepancies. Our results survive these exercises, and become even stronger in some cases.

In Column (4), we follow Hansen (2022, pp. 84–86) to calculate an index for each prefecture’s influence on the overall fitting of data. The index is calculated as follows. We estimate a cross-sectional RD regression that is numerically equivalent to the panel regression, Equation 2:

$$Y_i \equiv \frac{\sum_{t=2014}^{2019} \frac{Unrest_{it}}{L_{i,2010}}}{6} - \frac{\sum_{t=2011}^{2013} \frac{Unrest_{it}}{L_{i,2010}}}{3} = Reform_i + f(\tilde{p}_i; \zeta_{Reform}) + \varepsilon_i. \quad (\text{H1})$$

Then, the influence index is calculated as $d_i = \hat{Y}_i - \tilde{Y}_i$, where \hat{Y}_i is the predicted value based on a full-sample regression, while \tilde{Y}_i is the predicted value based on the leave-prefecture i -out regression. A high $|d_i|$ implies that prefecture i is an influential observation for the overall fitting of data. Thus, we drop prefectures with a high d_i : for reform prefectures we drop the top 25 percent, and for non-reform prefectures, we drop the top 10 percent. As shown by Column (4) of Table H3, this in facts accentuates our finding.

Table H3. Robustness: Addressing Potential Outliers

	(1)	(2)	(3)	(4)
Never having unrest recorded	Near the cutoff	w/ a diff. btw. population-based & manually-coded reforms	w/ high influence	
Reform \times Post	-1.419*** (-3.81)	-1.624*** (-4.62)	-1.834*** (-4.36)	-1.631*** (-7.29)
Control mean	3.395	3.750	3.769	4.053
Prefecture FE	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes	Yes
Observations	2,583	2,349	2,430	2,007

Note: This table checks the robustness of our results to potential outliers. Column (1) excludes prefectures that never had unrest events recorded in the CLB data. Column (2) removes prefectures that have urban population size very close to the reform cutoff, specifically, $|\tilde{p}_i| < 0.2$. Column (3) excludes prefectures whose population-based reform status does not agree with manually coded reform status. Column (4) follows Hansen (2022) to exclude prefectures that have a high influence on the overall fitting of data. Standard errors are clustered at the prefecture level and reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

H.4 Balancing Baseline Characteristics

In Section 4.1, we note that there remains some difference in baseline covariates between reform and non-reform prefectures, despite the inclusion of polynomial controls. Such imbalances could threaten our results if they are associated with differential trends in unrest. To address this issue, in this section, we use several strategies to balance the baseline covariates and explore the robustness of our results.

Table H4 reports our investigation. For comparison, Column (1) re-estimates Equation 2 using the sample that we have all data for baseline covariates, which is slightly smaller than the full sample. Column (2) directly controls for interactions between baseline covariates and year indicators in the model. Column (3) weights observations to the propensity score predicted by the baseline covariates. Column (4) implements the coarsened exact matching (CEM) proposed by Iacus et al. (2012), which weights observations such that reform and non-reform prefectures have

the same distributions of baseline covariates (we target tertiles). All approaches consistently show a negative effect of the *hukou* reform on unrest rates.

Table H4. Robustness: Covariates Balancing

	(1) Unrest/L	(2) Unrest/L	(3) Unrest/L	(4) Unrest/L
Reform × Post	-1.439*** (0.376)	-1.248*** (0.341)	-1.347* (0.763)	-1.685*** (0.430)
Balancing approach	-	Controls added	P-score	CEM
Control mean	3.395	3.395	3.100	3.482
Prefecture FE	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes
Polynomials	Yes	Yes	Yes	Yes
Observations	2,511	2,511	1,683	2,376

This table presents multiple approaches to control for baseline covariates, including share of male, share of urban residents, share of migrants, share of secondary sector workers, share of tertiary sector workers, and share of internet users. Column (1) presents the baseline result for the ease of comparison. Column (2) directly controls for these covariates interacted with year indicators in the regression. Column (3) weights observations to balance the propensity score predicted by covariates. Column (4) implements the coarsened exact matching (CEM, [Iacus et al., 2012](#)) to balance distributions of covariates. Standard errors are clustered at the prefecture level and reported in parentheses.

Note: * $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

I The Effect of the *Hukou* Reform on Outmigration

I.1 Cox Proportional Hazard Model

For robustness, we estimate a Cox proportional hazard model that is commonly used in survival analysis:

$$h(Outmigration_{jkt} | t, X) = h_0(t) \exp [\rho_1 (Reform_k \times Post15_t) + \rho_2 Reform_k + \rho_3 Post15_t]. \quad (I1)$$

$h(Outmigration_{jkt} | t, X)$ is the hazard rate of outmigration as of year t , conditional on a vector of explanatory variables, X , that one can see from the right-hand side of Equation I1. $h_0(t)$ is a common function of the time-at-risk. Following the semiparametric approach devised by Cox (1972), we leave the baseline hazard function $h_0(t)$ unrestricted and estimate the other coefficients by partial maximum likelihood. This way we take advantage of the tractability of the proportional hazard model, while allowing at the same time for significant flexibility in terms of functional form. Standard errors are clustered at the prefecture level.

Table I1 presents the results using the Cox model, which provides a consistent picture as in Table 4. The *hukou* reform reduced the hazard ratio of outmigration—according to Column (3)—by 53.2 percent. The effect is much larger for rural migrants than for urban migrants (Column (4) vs. Column (5)).

Table I1. Effect of *Hukou* Reform on Outmigration Rate: Cox Hazard Model

	Outmigration from 2010 residing prefecture				
	(1)	(2)	(3)	(4)	(5)
Reform × Post	-1.000*** (0.129)	-0.764*** (0.232)	-0.760*** (0.223)	-0.879*** (0.245)	-0.465* (0.254)
Sample	All migrants	All migrants	All migrants	Rural migrants	Urban migrants
Mfx. on hazard rate	-0.632	-0.534	-0.532	-0.585	-0.372
Polynomials		Yes	Yes	Yes	Yes
Stratified hazard function			Yes	Yes	Yes
Observations	100,875	100,875	100,875	58,647	42,228

Note: This table reports the effect of *hukou* reform on outmigration rate. When applicable, the hazard function is stratified by birth cohort, gender, educational attainment, and employment status. Standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

I.2 Addressing Measurement Error

As a robustness check, we exclude plausibly misclassified migrants from the basic migrants sample and re-estimate Equation 5. We identify plausibly misclassified migrants if individuals satisfy the following criteria:

1. *In 2010, living in prefectures that later had reforms.* Misclassified migrants are not likely to be natives of prefectures that did not have reforms in 2014. This is because their home prefectures are attractive places in China, so local residents are unlikely to relinquish their *hukou* there.
2. *Registering hukou in prefectures with lenient hukou transfer policies before the 2014 reform.* Misclassified migrants must have transferred their *hukou*, and they are more likely to transfer to prefectures that had lenient transfer policies. We identify such lenient prefectures using data from Fan (2019). Fan (2019) evaluates a transfer policy on a 0–3 scale, with 0 being the most restrictive and 3 being the most lenient. He distinguishes between the transfer policies of a prefecture's core district and its peripheral counties. Therefore, we define a prefecture as lenient if either its core district or its peripheral counties received a score above 2 in 2010 in Fan (2019)'s data.

Table I2 presents the results when excluding plausibly misclassified migrants. Compared to Table 4, the estimates in fact show larger negative effects of the *hukou* reform on outmigration rates, albeit with larger standard errors due to 30 percent smaller sample sizes. The effects are again driven by rural migrants, indicating that the heterogeneous effects between rural and urban migrants are not due to differential measurement error between the two groups.

Table I2. The *Hukou* Reform and Outmigration: Addressing Measurement Error

	Outmigration from 2010 residing prefecture				
	(1)	(2)	(3)	(4)	(5)
Reform × Post	-0.072* (0.039)	-0.072* (0.039)	-0.074* (0.041)	-0.106* (0.056)	-0.025 (0.025)
Sample	All migrants	All migrants	All migrants	Rural migrants	Urban migrants

J Causal Mediation Analysis

J.1 Conventional Approach

Suppose that the unit of analysis is denoted by i . This does not lose generality. In a panel, one can define $i \equiv (j, t)$ where j and t index units and periods, respectively. For brevity, we let i index individuals in subsequent discussion.

Let Y_i denote the outcome variable. T_i is the treatment of interest. M_i is a mechanism variable. We are interested in the causal effect of that T_i has on Y_i and how much of this effect is achieved by T_i intervening in M_i . To clarify parameters of interest, consider a potential outcome framework with linear heterogeneity of causal effects:

$$Y_i(T_i, M_i) = \tau_i T_i + \gamma_i M_i + u_i, \quad (\text{J1})$$

$$M_i(T_i) = \pi_i T_i + v_i. \quad (\text{J2})$$

Therefore,

$$Y_i(T_i) \equiv Y_i(T_i, M_i(T_i)) = (\tau_i + \gamma_i \pi_i) T_i + u_i + \gamma_i v_i \equiv \beta_i T_i + \eta_i, \quad (\text{J3})$$

where $\beta_i = \tau_i + \gamma_i \pi_i$ and $\eta_i = u_i + \gamma_i v_i$.

DEFINITION J1 (Causal Parameters of Interest).

1. The total effect is $\beta_i = \tau_i + \gamma_i \pi_i$, thus, the average total effect (ATE) is $E(\beta_i) = E(\tau_i) + E(\gamma_i \pi_i)$.
2. The indirect effect that is due to mechanism variable M_i is $\gamma_i \pi_i$, thus, the average indirect effect (AIE) is $E(\gamma_i \pi_i)$.
3. The direct effect that is not due to mechanism variable M_i is τ_i , thus, the average direct effect (ADE) is $E(\tau_i)$.

Note that $\beta_i = \tau_i + \gamma_i \pi_i$ and $ATE = ADE + AIE$.

We further assume that T_i is exogenous. It abstracts away from identification issues of the effects of T_i , allowing us to focus on identification of mediation effects.

ASSUMPTION J1 (Treatment Exogeneity). $\{Y_i(t', m), M_i(t)\} \perp\!\!\!\perp T_i$, for all t, t' , and m .

The conventional approach, popularized by Baron and Kenny (1986), is to estimate the following linear simultaneous equations model (LSEM):

$$Y_i = \alpha_1 + \beta T_i + e_{i1}, \quad (\text{J4})$$

$$Y_i = \alpha_2 + \tau T_i + \gamma M_i + e_{i2}, \quad (\text{J5})$$

$$M_i = \alpha_3 + \pi T_i + e_{i3}. \quad (\text{J6})$$

The change in estimated coefficient on T_i after including M_i is interpreted as AIE, that is,

$$\widehat{AIE} \equiv \hat{\beta} - \hat{\tau} = \hat{\gamma} \hat{\pi}. \quad (\text{J7})$$

\hat{w} denotes the OLS estimand of coefficient w , i.e., probability limit of OLS estimator. The equality is by the properties of least squares, which is the estimated effect of M_i on Y_i times the estimated effect of T_i on M_i . However, strong assumptions are required in order to interpret \widehat{AIE} as AIE (e.g., among others, Imai et al., 2011).

To see this, first consider $\hat{\beta}$.

$$\hat{\beta} = \frac{Cov(T_i, Y_i)}{Var(T_i)} \quad (\text{J8})$$

$$= \frac{Cov(T_i, \beta_i T_i + \eta_i)}{Var(T_i)} \quad (\text{J9})$$

$$= E(\beta_i). \quad (\text{J10})$$

The second equality is by plugging in the potential outcome Equation J3. The third equality is by Assumption J1. Thus, $\hat{\beta}$ identifies the ATE.

Next, consider $\hat{\tau}$. By the property of least squares,

$$\hat{\tau} = \frac{Cov(T_i, Y_i - \hat{\gamma} M_i)}{Var(T_i)} = \hat{\beta} - \hat{\gamma} \hat{\pi}, \quad (\text{J11})$$

where $\hat{\pi} = E(\pi_i)$ identifies the population average effect of T_i on M_i under Assumption J1. Now, we derive $\hat{\gamma}$. Let $L(R | T)$ denote the linear projection of R on T and constant 1, and \tilde{R} is the linear projection residual, namely, $\tilde{R} = R - L(R | T)$. By Assumption J1 and Equation J2, $L(M_i | T_i) = E(M_i | T_i)$, i.e., the linear projection recovers the conditional mean.¹⁷ $\hat{\gamma}$ has the following expression:

$$\hat{\gamma} = \frac{E(\tilde{M}_i Y_i)}{E(\tilde{M}_i^2)} \quad (\text{J12})$$

¹⁷ $E(M_i | T_i) = E(\pi_i | T_i)T_i + E(v_i | T_i) = E(\pi_i)T_i + E(v_i)$ is linear.

$$= \frac{E\left[\tilde{M}_i(\tau_i T_i + \gamma_i M_i + u_i)\right]}{E(\tilde{M}_i^2)} \quad (\text{J13})$$

$$= \frac{E(\tilde{M}_i M_i \gamma_i)}{E(\tilde{M}_i^2)} + \frac{E(\tilde{M}_i T_i \tau_i)}{E(\tilde{M}_i^2)} + \frac{E(\tilde{M}_i u_i)}{E(\tilde{M}_i^2)}. \quad (\text{J14})$$

The first term is a weighted average of γ_i , albeit different from the population average $E(\gamma_i)$. The second term picks up the causal effect of T_i , representing a contamination bias as in Goldsmith-Pinkham et al. (2022). The third term is the endogeneity bias. Therefore, $\hat{\gamma}$ is biased for $E(\gamma_i)$, and in fact, it does not even identify a causal effect of M_i on Y_i , regardless of weighting schemes. Such bias is expected, since there is no exogenous variation in M_i conditional on T_i that warrants identification.

Taken together,

$$\widehat{AIE} = \hat{\beta} - \hat{\tau} \quad (\text{J15})$$

$$= \left[\frac{E(\tilde{M}_i M_i \gamma_i)}{E(\tilde{M}_i^2)} + \frac{E(\tilde{M}_i T_i \tau_i)}{E(\tilde{M}_i^2)} + \frac{E(\tilde{M}_i u_i)}{E(\tilde{M}_i^2)} \right] E(\pi_i) \quad (\text{J16})$$

$$\neq AIE \quad (\text{J17})$$

$$\equiv E(\gamma_i \pi_i) = E(\gamma_i) E(\pi_i) - \text{Cov}(\gamma_i, \pi_i). \quad (\text{J18})$$

\widehat{AIE} is biased for AIE . The bias is expressed as:

$$\text{Bias} = \widehat{AIE} - AIE = \underbrace{[\hat{\gamma} - E(\gamma_i)] E(\pi_i)}_{\text{bias 1}} + \underbrace{\text{Cov}(\gamma_i, \pi_i)}_{\text{bias 2}}. \quad (\text{J19})$$

There are two sources of bias. Bias 1 is due to that $\hat{\gamma}$ does not identify $E(\gamma_i)$. Bias 2 is a mechanical consequence of LSEM. The LSEM overlooks heterogeneity in γ_i and uses an *average* slope of Y_i for M_i , $E(\gamma_i)$, to evaluate M_i 's marginal contribution to Y_i , π_i . This produces bias if π_i is correlated with γ_i : Consider a positive correlation, the average slope systematically understates contributions of high π_i 's and overstates contributions of low π_i 's.

Researchers often assume homogeneity of γ_i , which eliminates bias 2. But bias 1 still exists. Imai et al. (2011) show a sufficient condition to eliminate this bias is a “sequential ignorability” assumption.

ASSUMPTION J2 (Sequential Ignorability). $Y_i(t', m) \perp\!\!\!\perp M_i(t) \mid T_i = t, \forall t, t', m$.

That said, M_i is exogenous conditional on T_i , indicating that there is no other post-treatment confounders. With this assumption, we can derive the following results.

$$E(\tilde{M}_i T_i \tau_i) = E[E(\tilde{M}_i T_i \tau_i | T_i)] \quad (\text{J20})$$

$$= E[E(\tilde{M}_i T_i | T_i) E(\tau_i | T_i)] \quad (\text{J21})$$

$$= E(\tilde{M}_i T_i) E(\tau_i) \quad (\text{J22})$$

$$= 0. \quad (\text{J23})$$

The first equality is by the law of iterated expectations (LIE). The second equality is by Assumption J2. The third equality is by Assumption J1. The fourth equality is by the orthogonality of linear projection residuals. Using similar tricks yields

$$E(\tilde{M}_i u_i) = E[E(\tilde{M}_i u_i | T_i)] \quad (\text{J24})$$

$$= E[E(\tilde{M}_i | T_i) E(u_i | T_i)] \quad (\text{J25})$$

$$= E(\tilde{M}_i) E(u_i) \quad (\text{J26})$$

$$= 0. \quad (\text{J27})$$

Together with homogeneity assumption $\gamma_i = \gamma$, $\hat{\gamma} = \gamma = E(\gamma_i)$. Therefore, $\widehat{AIE} = AIE$.¹⁸

J.2 IV-Augmented Approach

The plausibility of Assumption J2 is questionable. Without this assumption, the key problem is that $\hat{\gamma}$ is not consistent for a causal effect of M_i on Y_i , not to mention $E(\gamma_i)$. We propose to use an IV for M_i , denoted by Z_i , to identify a causal effect of M_i on Y_i . We want to upfront regarding potential issues in this approach. First of all, the validity of IV requires additional assumptions. Second, provided that IV is valid, it in general does not identify the population average effect $E(\gamma_i)$, unless γ_i is constant or other assumptions are imposed. Nonetheless, we view the IV-augmented approach as bringing some improvements to the conventional approach.

We extend the potential outcome framework to incorporate IV Z_i .

$$Y_i(T_i, M_i) = \tau_i T_i + \gamma_i M_i + u_i, \quad (\text{J28})$$

$$M_i(T_i, Z_i) = \pi_i T_i + \theta_i Z_i + v_i. \quad (\text{J29})$$

¹⁸This result does not require the homogeneity assumption. With Assumption J2, one can further show that $E(\tilde{M}_i M_i \gamma_i) = E(\tilde{M}_i M_i \gamma_i | T_i) = E(\tilde{M}_i M_i) E(\gamma_i) = E(\tilde{M}_i^2) E(\gamma_i)$. Thus, $\hat{\gamma} = E(\gamma_i)$, hence, bias 1 = 0. Assumption J2 also implies that $\gamma_i \perp\!\!\!\perp \pi_i | T_i$. Thus, bias 2 = $E[E(\gamma_i \pi_i | T_i)] - E(\gamma_i) E(\pi_i) = E[E(\gamma_i | T_i) E(\pi_i | T_i)] - E(\gamma_i) E(\pi_i) = 0$, where the first equality is by the definition of covariance and the LIE, the second equality is by $\gamma_i \perp\!\!\!\perp \pi_i | T_i$, and the last equality is by Assumption J1. Taken together, $\widehat{AIE} = AIE$, even if the homogeneity assumption is not made.

Therefore, we have the following reduced-form model:

$$Y_i(T_i, Z_i) \equiv Y_i(T_i, M_i(T_i, Z_i)) \quad (\text{J30})$$

$$= (\pi_i + \gamma_i \pi_i) T_i + \gamma_i \theta_i Z_i + (u_i + \gamma_i v_i) \quad (\text{J31})$$

$$= \beta_i T_i + \rho_i Z_i + \eta_i, \quad (\text{J32})$$

where $\beta_i = \tau_i + \gamma_i \pi_i$, $\rho_i = \gamma_i \theta_i$, and $\eta_i = u_i + \gamma_i v_i$.

We impose the following assumptions.

ASSUMPTION J3 (Treatment Exogeneity). $\{Y_i(t', m), M_i(t, z), Z_i\} \perp\!\!\!\perp T_i$, for all t, t', m , and z .

ASSUMPTION J4 (IV Validity).

1. (Independence) $\{Y_i(t', m), M_i(t, z)\} \perp\!\!\!\perp Z_i$ for all t, t', m , and z .
2. (Exclusion) $Y_i(t, m) |_z = Y_i(t, m) |_{z'}$ for all z and z' .
3. (Relevance) $E(\theta_i) \neq 0$.
4. (Monotonicity) Either $\Pr(\theta_i \geq 0) = 1$ or $\Pr(\theta_i \leq 0) = 1$.

PROPOSITION J1. *Under Assumptions J3 and J4, two stage least squares (2SLS) estimation of the LSEM, with M_i instrumented by Z_i , yields*

$$\widehat{AIE} = \hat{\beta} - \hat{\tau} = \underbrace{\hat{\gamma} \hat{\pi}}_{AIE} + \underbrace{[\hat{\gamma} - E(\gamma_i)] E(\pi_i)}_{bias 1} - \underbrace{Cov(\gamma_i, \pi_i)}_{bias 2}, \quad (\text{J33})$$

where $\hat{\beta} = E(\beta_i)$ and $\hat{\gamma} = E\left[\frac{\theta_i}{E(\theta_i)} \gamma_i\right]$. $\hat{\beta} - \hat{\tau}$ identifies AIE if (i) γ_i is constant, or (ii) $\{\theta_i, \pi_i\} \perp\!\!\!\perp \gamma_i$.

Proof. By Assumption J3, it is straightforward to show that

$$\hat{\beta} = \frac{Cov(T_i, Y_i)}{Var(T_i)} = E(\beta_i), \quad (\text{J34})$$

$$\hat{\pi} = \frac{Cov(T_i, M_i)}{Var(T_i)} = E(\pi_i). \quad (\text{J35})$$

By the property of least squares, $\hat{\tau} = \frac{Cov(T_i, Y_i - \hat{\gamma} M_i)}{Var(T_i)} = \hat{\beta} - \hat{\gamma} \hat{\pi}$. We now derive the 2SLS estimand $\hat{\gamma}$. It can be written as:

$$\hat{\gamma} = \frac{E(\tilde{Z}_i Y_i)}{E(\tilde{Z}_i M_i)}, \quad (\text{J36})$$

where $\tilde{Z}_i = Z_i - L(Z_i \mid T_i)$ is the linear projection residual. By Assumption J3, $E(Z_i \mid T_i) = E(Z_i)$ is linear, thus, $L(Z_i \mid T_i) = E(Z_i \mid T_i)$. We can show the following result.

$$E(\tilde{Z}_i Y_i) = E[\tilde{Z}_i(\beta_i T_i + \rho_i Z_i + \eta_i)] \quad (\text{J37})$$

$$= E(\tilde{Z}_i T_i)E(\beta_i) + E(\tilde{Z}_i Z_i)E(\rho_i) + E(\tilde{Z}_i)E(\eta_i), \quad (\text{J38})$$

$$= E(\tilde{Z}_i Z_i)E(\rho_i). \quad (\text{J39})$$

The second equality is by Assumptions J3 and J4(1). The third equality uses the fact that $\tilde{Z}_i = Z_i - E(Z_i \mid T_i) = Z_i - E(Z_i)$. With similar tricks, the following result follows:

$$E(\tilde{Z}_i M_i) = E[\tilde{Z}_i(\pi_i T_i + \theta_i Z_i + u_i)] \quad (\text{J40})$$

$$= E(\tilde{Z}_i T_i)E(\pi_i) + E(\tilde{Z}_i Z_i)E(\theta_i) + E(\tilde{Z}_i)E(u_i), \quad (\text{J41})$$

$$= E(\tilde{Z}_i Z_i)E(\theta_i). \quad (\text{J42})$$

Taken together,

$$\hat{\gamma} = \frac{E(\rho_i)}{E(\theta_i)} = \frac{E(\theta_i \gamma_i)}{E(\theta_i)}. \quad (\text{J43})$$

An alternative expression for $\hat{\gamma}$ is

$$\hat{\gamma} = \frac{E(\tilde{Z}_i M_i \gamma_i)}{E(\tilde{Z}_i M_i)}. \quad (\text{J44})$$

Therefore,

$$\widehat{AIE} = \hat{\beta} - \hat{\tau} \quad (\text{J45})$$

$$= \hat{\gamma} E(\pi_i) \quad (\text{J46})$$

$$= \hat{\gamma} E(\pi_i) + E(\gamma_i \pi_i) - Cov(\gamma_i, \pi_i) + E(\gamma_i)E(\pi_i) \quad (\text{J47})$$

$$= \underbrace{E(\gamma_i \pi_i)}_{\text{AIE}} + \underbrace{[\hat{\gamma} - E(\gamma_i)] E(\pi_i)}_{\text{bias 1}} - \underbrace{Cov(\gamma_i, \pi_i)}_{\text{bias 2}}, \quad (\text{J48})$$

where $\hat{\gamma} = \frac{E(\tilde{Z}_i M_i \gamma_i)}{E(\tilde{Z}_i M_i)} = \frac{E(\theta_i \gamma_i)}{E(\theta_i)}$. It is obvious that bias 1 = bias 2 = 0 if (i) γ_i is constant, or (ii) $\{\theta_i, \pi_i\} \perp\!\!\!\perp \gamma_i$, making $\widehat{AIE} = AIE$. ■

Proposition J1 implies that even with instrumentation, \widehat{AIE} , the change in the coefficient on T_i after controlling for instrumented M_i , may still be biased for the AIE. Specifically, the bias comes from two sources.

- Bias 1 (“IV bias”).** The first bias comes from the discrepancy between the IV-identified average effect and the population average effect, i.e., $\text{plim } \hat{\gamma}$ versus $E(\gamma_i)$. Intuitively, this bias occurs because the IV identifies the effect of M_i on Y_i within a subpopulation that may differ from the

population in which the effect of T_i on Y_i is identified. Therefore, without assuming constant γ_i , the IV-identified effect of M_i on Y_i cannot be perfectly generalized to the entire population.

2. **Bias 2 (“ecological bias”).** The second bias is due to the correlation between γ_i and π_i . This is the classical ecological bias, which occurs when the characteristics of a population are attributed to an individual (Glynn, 2012). The intuition is as follows. Ideally, one would like to use γ_i , *individual-specific* effect of M_i on Y_i , as the loading on π_i to evaluate the contribution of the treatment effect on M_i to the total treatment effect. However, the linear regression can only use $\hat{\gamma}$, an *average* impact of M_i on Y_i , as the loading on π_i . As a result, the linear regression overlooks co-movement of γ_i and π_i , thus, it may systematically mis-measure the importance of the treatment-induced change in M_i to the outcome at the individual level and also at the aggregate level.¹⁹ Clearly, by assuming constant γ_i , such bias is zero.

Assuming γ_i to be homogeneous eliminates bias 1 and bias 2 and yields Proposition 1.

J.3 Extension: Regression Discontinuity

In light of the research design of this paper, we extend the results above to RDDs. If one takes a local randomization view of RDDs, then our results above can be directly applied within a very narrow bandwidth around the cutoff. No polynomial controls are necessary, provided rich data are available even after bandwidth restrictions. In the following, we focus our attention on parametric RDDs, which impose some functional form assumptions on the conditional means of potential outcomes and thus necessitate polynomial controls.

Let r_i denote the running variable. $T_i = \mathbb{1}\{r_i \geq 0\}$. $\mathbf{R}_i = (r_i, r_i^2, \dots, r_i^p)$ is a set of power functions of r_i , up to order p . Also define $\mathbf{R}_i^{(0)} = (1, \mathbf{R}_i)$. $\mathbf{X}_i = [\mathbf{R}_i T_i, \mathbf{R}_i (1 - T_i)]'$ is the polynomial function to be included in RD regressions. Also define $\mathbf{X}_i^{(0)} = [\mathbf{R}_i^{(0)} T_i, \mathbf{R}_i^{(0)} (1 - T_i)]'$. With the introduction of running variable, the LSEM to estimate now becomes:

$$Y_i = \alpha_1 + \beta T_i + \mathbf{X}_i' \zeta_1 + e_{i1}, \quad (\text{J49})$$

$$Y_i = \alpha_2 + \tau T_i + \gamma M_i + \mathbf{X}_i' \zeta_2 + e_{i2}, \quad (\text{J50})$$

$$M_i = \alpha_3 + \pi T_i + \mathbf{X}_i' \zeta_3 + e_{i3}. \quad (\text{J51})$$

In RDDs, parameters of interest are causal effects at cutoff $r_i = 0$. They are defined as follows.

DEFINITION J2 (Parameters of Interest in RDDs).

¹⁹For instance, suppose $Cov(\gamma_i, \pi_i) > 0$ and $\gamma_i, \pi_i > 0$. Then, within the low- γ_i group, the contribution of the treatment-induced change in M_i (i.e., π_i) is systematically overstated, while within the high- γ_i group, the contribution is systematically understated.

1. The total effect is $\beta_i = \tau_i + \gamma_i \pi_i$. ATE is defined as the average total effect conditional at $r_i = 0$, $E(\beta_i | r_i = 0) = E(\tau_i | r_i = 0) + E(\gamma_i \pi_i | r_i = 0)$.
2. The indirect effect that is due to mechanism variable M_i is $\gamma_i \pi_i$. AIE is defined as the average indirect effect at cutoff, $E(\gamma_i \pi_i | r_i = 0)$.
3. The direct effect that is not due to mechanism variable M_i is τ_i . ADE is defined as the average direct effect at cutoff, $E(\tau_i | r_i = 0)$.

ASSUMPTION J5 (Linearity of Conditional Means).

1. $E[Y_i(1, Z_i) | r_i]$ and $E[Y_i(0, Z_i) | r_i]$ are linear in $\mathbf{R}_i^{(0)}$.
2. $E[M_i(1, Z_i) | r_i]$ and $E[M_i(0, Z_i) | r_i]$ are linear in $\mathbf{R}_i^{(0)}$.

ASSUMPTION J6 (IV Validity).

1. (Independence) $\{Y_i(t', m), M_i(t, z)\} \perp\!\!\!\perp Z_i | r_i$ for all t, t', m , and z .
2. (Exclusion) $Y_i(t, m) |_z = Y_i(t, m) |_{z'}$ for all z and z' .
3. (Relevance) $E(\tilde{Z}_i M_i) \neq 0$, where $\tilde{Z}_i = Z_i - L \left[Z_i | \mathbf{X}_i^{(0)} \right]$ is the linear projection residual.
4. (Monotonicity) Either $\Pr(\theta_i \geq 0) = 1$ or $\Pr(\theta_i \leq 0) = 1$.

ASSUMPTION J7 (IV Linearity). $E(Z_i | r_i)$ is linear in $\mathbf{X}_i^{(0)}$.

Assumption J5 specifies conditional means of potential outcomes. It implies the continuity of conditional means. The assumption also allow us to abstract away from estimation complications in parametric RDDs, e.g., bandwidth selection. Assumption J6 warrants validity of IV. Importantly, independence only needs to hold conditional on running variable r_i . Assumption J7 assumes linearity of IV, as in Ishimaru (2024).

PROPOSITION J2. *Under Assumptions J5, J6, and J7, 2SLS estimation of the LSEM, with M_i instrumented by Z_i , yields*

$$\begin{aligned} \widehat{AIE} &= \hat{\beta} - \hat{\tau} = \hat{\gamma} \hat{\pi} \\ &= \underbrace{E(\gamma_i \pi_i | r_i = 0)}_{AIE} + \underbrace{[\hat{\gamma} - E(\gamma_i | r_i = 0)] E(\pi_i | r_i = 0)}_{bias 1} - \underbrace{Cov(\gamma_i, \pi_i | r_i = 0)}_{bias 2}, \end{aligned} \quad (J52)$$

where $\hat{\beta} = E(\beta_i | r_i = 0)$ and $\hat{\gamma} = \frac{E(\tilde{Z}_i M_i \gamma_i)}{E(\tilde{Z}_i M_i)} = \frac{E[Var(Z_i | r_i) E(\theta_i \gamma_i | r_i)]}{E[Var(Z_i | r_i) E(\theta_i | r_i)]}$. \widehat{AIE} identifies AIE if (i) γ_i is constant, or (ii) $\{\theta_i, \pi_i\} \perp\!\!\!\perp \gamma_i | r_i$ and $\gamma_i \perp\!\!\!\perp r_i$.

Proof. By Assumption J5, linear regression identifies conditional means of potential outcomes. Thus, a linear regression of Y_i on 1, T_i and \mathbf{X}_i yields

$$\hat{\beta} = \lim_{r \downarrow 0} E[Y_i(1, Z_i) | r_i = r] - \lim_{r \uparrow 0} E[Y_i(0, Z_i) | r_i = r] \quad (\text{J53})$$

$$= \lim_{r \downarrow 0} E[\beta_i + \rho_i Z_i + \eta_i | r_i = r] - \lim_{r \uparrow 0} E[\rho_i Z_i + \eta_i | r_i = r] \quad (\text{J54})$$

$$= E(\beta_i | r_i = 0), \quad (\text{J55})$$

where the first equality is by linearity assumed in Assumption J5, the second equality plugs in potential outcomes, and the last equality uses continuity implied by J5. Similarly, one can show that $\hat{\pi} = E(\pi | r_i = 0)$.

By the property of least square, $\hat{\tau} = \hat{\beta} - \hat{\gamma}\hat{\pi}$. Now derive $\hat{\gamma} = \frac{E(\tilde{Z}_i Y_i)}{E(\tilde{Z}_i M_i)}$, where $\tilde{Z}_i = Z_i - L[Z_i | \mathbf{X}_i^{(0)}]$. $\hat{\gamma}$ is written as:

$$\hat{\gamma} = \frac{E[\tilde{Z}_i(\beta_i T_i + \rho_i Z_i + \eta_i)]}{E[\tilde{Z}_i(\pi_i T_i + \theta_i Z_i + v_i)]}. \quad (\text{J56})$$

Analyze term by term.

$$E(\tilde{Z}_i T_i \beta_i) = E[E(\tilde{Z}_i T_i \beta_i | r_i)] = E[E(\tilde{Z}_i | r_i) T_i E(\beta_i | r_i)] = 0. \quad (\text{J57})$$

The first equality is by the LIE. The second equality is by Assumption J6(1) and the fact that T_i is completely determined by r_i in a RDD. The last equality is due to Assumption J7 that implies $L[Z_i | \mathbf{X}_i^{(0)}] = E[Z_i | \mathbf{X}_i^{(0)}]$. Similarly,

$$E(\tilde{Z}_i T_i \pi_i) = 0, \quad (\text{J58})$$

$$E(\tilde{Z}_i \eta_i) = 0, \quad (\text{J59})$$

$$E(\tilde{Z}_i v_i) = 0. \quad (\text{J60})$$

Therefore,

$$\hat{\gamma} = \frac{E(\tilde{Z}_i Z_i \theta_i \gamma_i)}{E(\tilde{Z}_i Z_i \theta_i)} = \frac{E[E(\tilde{Z}_i Z_i | r_i) E(\theta_i \gamma_i | r_i)]}{E[E(\tilde{Z}_i Z_i | r_i) E(\theta_i | r_i)]} = \frac{E[Var(Z_i | r_i) E(\theta_i \gamma_i | r_i)]}{E[Var(Z_i | r_i) E(\theta_i | r_i)]}. \quad (\text{J61})$$

An alternative expression for $\hat{\gamma}$ is

$$\hat{\gamma} = \frac{E(\tilde{Z}_i M_i \gamma_i)}{E(\tilde{Z}_i M_i)}. \quad (\text{J62})$$

Taken together,

$$\hat{\beta} - \hat{\tau} = \hat{\gamma}E(\pi_i | r_i = 0) \quad (\text{J63})$$

$$= \hat{\gamma}E(\pi_i | r_i = 0) + E(\gamma_i \pi_i | r_i = 0) - Cov(\gamma_i, \pi_i | r_i = 0) + E(\gamma_i | r_i = 0)E(\pi_i | r_i = 0) \quad (\text{J64})$$

$$= \underbrace{E(\gamma_i \pi_i | r_i = 0)}_{\text{AIE}} + \underbrace{[\hat{\gamma} - E(\gamma_i | r_i = 0)] E(\pi_i | r_i = 0)}_{\text{bias 1}} - \underbrace{Cov(\gamma_i, \pi_i | r_i = 0)}_{\text{bias 2}}, \quad (\text{J65})$$

where $\hat{\gamma} = \frac{E(\tilde{Z}_i M_i \gamma_i)}{E(\tilde{Z}_i M_i)} = \frac{E[Var(Z_i | r_i) E(\theta_i \gamma_i | r_i)]}{E[Var(Z_i | r_i) E(\theta_i | r_i)]}$. It is obvious that bias 1 = bias 2 = 0 if (i) γ_i is constant, or (ii) $\{\theta_i, \pi_i\} \perp\!\!\!\perp \gamma_i | r_i$ and $\gamma_i \perp\!\!\!\perp r_i$. ■

Proposition 2 assumes that γ_i is constant.

J.4 Sensitivity Test

Our results imply that $\hat{\beta} - \hat{\tau}$ identifies AIE if γ_i is homogeneous across i . We maintain this assumption to perform our analysis. However, this assumption may be overly strong in many applications. In this section, we gauge under what conditions $\hat{\beta} - \hat{\tau}$ is still informative about AIE even if γ_i is heterogeneous.

Consider our baseline setups. Note that the bias is expressed as

$$Bias = \hat{\gamma}\hat{\pi} - \underbrace{E(\gamma_i \pi_i)}_{\text{AIE}} \quad (\text{J66})$$

$$= [\hat{\gamma} - E(\gamma_i)] \hat{\pi} - Cov(\gamma_i, \pi_i) \quad (\text{J67})$$

$$= Cov(\phi_i, \gamma_i)\hat{\pi} - Cov(\gamma_i, \pi_i) \quad (\text{J68})$$

$$= \rho_{\phi\gamma}\sigma_\phi\sigma_\gamma\hat{\pi} - \rho_{\gamma\pi}\sigma_\gamma\sigma_\pi, \quad (\text{J69})$$

where $\phi_i = \frac{\tilde{Z}_i M_i}{E(\tilde{Z}_i M_i)}$, $\rho_{\phi\gamma} = Corr(\phi_i, \gamma_i)$, $\rho_{\gamma\pi} = Corr(\gamma_i, \pi_i)$, $\sigma_\phi = SD(\phi_i)$, $\sigma_\gamma = SD(\gamma_i)$, and $\sigma_\pi = SD(\pi_i)$. If there is knowledge of $Cov(\phi_i, \gamma_i)$ and $Cov(\gamma_i, \pi_i)$, together with $\hat{\gamma}\hat{\pi}$, we can de-bias or at least bound AIE. We propose one approach below.

ASSUMPTION J8 (Sign and Distributional Restrictions). All γ_i 's have the same sign. All π_i 's have the same sign. γ_i and π_i are uniformly distributed.

PROPOSITION J3. Under Assumption J8, for every given $\rho_{\phi\gamma}$ and $\rho_{\gamma\pi}$, AIE is identified by estimand

$$\widehat{\widehat{AIE}} = \left[\frac{\sqrt{3} \operatorname{sgn}(\gamma_i) \hat{\gamma}}{\sqrt{3} \operatorname{sgn}(\gamma_i) + \rho_{\phi\gamma} \hat{\sigma}_\phi} + \frac{\rho_{\gamma\pi} \hat{\sigma}_\phi \operatorname{sgn}(\pi_i)}{\sqrt{3}} \right] \hat{\pi}. \quad (\text{J70})$$

where $\hat{\sigma}_\phi = \operatorname{plim} \sqrt{\frac{1}{n} \sum_{i=1}^n \left(\frac{\tilde{Z}_i M_i}{\frac{1}{n} \sum_{i=1}^n \tilde{Z}_i M_i} - 1 \right)^2}$, and $\operatorname{sgn}(\gamma_i)$ and $\operatorname{sgn}(\pi_i)$ respectively give signs of γ_i and π_i .

Proof. By the expression of Bias, $\hat{\gamma} \hat{\pi} - E(\gamma_i) \hat{\pi} = \rho_{\phi\gamma} \sigma_\phi \sigma_\gamma \hat{\pi}$. Under Assumption J8, $E(\gamma_i) = \sqrt{3} \operatorname{sgn}(\gamma_i) \sigma_\gamma$. Thus, $\sigma_\gamma = \frac{\hat{\gamma}}{\sqrt{3} \operatorname{sgn}(\gamma_i) + \rho_{\phi\gamma} \sigma_\phi}$. Since π_i satisfies a uniform distribution and $\hat{\pi} = E(\pi_i)$, $\sigma_\pi = \frac{\hat{\pi} \operatorname{sgn}(\pi_i)}{\sqrt{3}}$. Taken together,

$$AIE = \left[\frac{\sqrt{3} \operatorname{sgn}(\gamma_i) \hat{\gamma}}{\sqrt{3} \operatorname{sgn}(\gamma_i) + \rho_{\phi\gamma} \sigma_\phi} + \frac{\rho_{\gamma\pi} \sigma_\phi \operatorname{sgn}(\pi_i)}{\sqrt{3}} \right] \hat{\pi}. \quad (\text{J71})$$

In this expression, σ_ϕ is unknown. However, consider estimator $\sqrt{\frac{1}{n} \sum_{i=1}^n \left(\frac{\tilde{Z}_i M_i}{\frac{1}{n} \sum_{i=1}^n \tilde{Z}_i M_i} - 1 \right)^2}$, the probability limit of which is denoted by $\hat{\sigma}_\phi$. By the weak law of large numbers, $\hat{\sigma}_\phi = \sigma_\phi$. As such, AIE is identified by

$$\widehat{\widehat{AIE}} = \left[\frac{\sqrt{3} \operatorname{sgn}(\gamma_i) \hat{\gamma}}{\sqrt{3} \operatorname{sgn}(\gamma_i) + \rho_{\phi\gamma} \hat{\sigma}_\phi} + \frac{\rho_{\gamma\pi} \hat{\sigma}_\phi \operatorname{sgn}(\pi_i)}{\sqrt{3}} \right] \hat{\pi}. \quad (\text{J72})$$

for every given $\rho_{\phi\gamma}$ and $\rho_{\gamma\pi}$. ■

The following proposition extends to the case of RDDs.

PROPOSITION J4. Suppose $\{\gamma_i, \pi_i\} \perp\!\!\!\perp r_i$. Under Assumption J8, for every given $\rho_{\phi\gamma}$ and $\rho_{\gamma\pi}$, AIE is identified by estimand

$$\widehat{\widehat{AIE}} = \left[\frac{\sqrt{3} \operatorname{sgn}(\gamma_i) \hat{\gamma}}{\sqrt{3} \operatorname{sgn}(\gamma_i) + \rho_{\phi\gamma} \hat{\sigma}_\phi} + \frac{\rho_{\gamma\pi} \hat{\sigma}_\phi \operatorname{sgn}(\pi_i)}{\sqrt{3}} \right] \hat{\pi}. \quad (\text{J73})$$

where $\hat{\sigma}_\phi = \operatorname{plim} \sqrt{\frac{1}{n} \sum_{i=1}^n \left(\frac{\tilde{Z}_i M_i}{\frac{1}{n} \sum_{i=1}^n \tilde{Z}_i M_i} - 1 \right)^2}$, and $\operatorname{sgn}(\gamma_i)$ and $\operatorname{sgn}(\pi_i)$ respectively give signs of γ_i and π_i .

Proof. By assuming $\{\gamma_i, \pi_i\} \perp\!\!\!\perp r_i$, the proof is the same as in basic setups. ■

Proposition 3 is a simplified version of Propositions J3 and J4. It assumes $\gamma_i \perp\!\!\!\perp \pi_i$ and thus $\rho_{\gamma\pi} = 0$.

K Additional Empirical Results for Causal Mediation Analysis

K.1 Balance Tests for Trade Shocks

We discuss if the trade shocks measured in Equation 15 can be viewed as quasi-exogenous triggers of labor unrest. Recall that the trade shock is constructed as a shift-share variable:

$$TradeShock_{it} = \sum_k \underbrace{\frac{X_{ik,2010}^{CN}}{L_{i,2010}}}_{\text{share}} \times \underbrace{\frac{\Delta X_{kt}^{ROW}}{X_{k,2010}^{CN}}}_{\text{shift}} \equiv \sum_k s_{ik} g_{kt}, \quad (\text{K1})$$

where $s_{ik} = \frac{X_{ik,2010}^{CN}}{L_{i,2010}}$ and $g_{kt} = \frac{\Delta X_{kt}^{ROW}}{X_{k,2010}^{CN}}$. The “shift” component, g_{kt} , is the growth in global demand for product k in year t , *relative* to the industry size of product k in China in 2010. It is apportioned to prefectures by the “share” term, s_{ik} , which reflects the initial specialization of prefecture i .

[Borusyak et al. \(2022\)](#) show that the quasi-exogeneity of $TradeShock_{it}$ can follow from the quasi-exogeneity of the shift, g_{kt} . Intuitively, this condition is violated if products with high g_{kt} are systematically produced in regions with differential dynamics of labor unrest. To test the quasi-exogeneity of g_{kt} , we conduct balance tests following ([Borusyak et al., 2022](#)). Specifically, we estimate the following product-level regression model:

$$q_k = \beta_0 + \beta_1 g_{kt} + \mu_t + \varepsilon_k. \quad (\text{K2})$$

$q_k = \sum_i \frac{s_{ik}}{\sum_i s_{ik}} v_i$. v_i is a covariate of prefecture i , thus, q_k captures the s_{ik} -weighted average covariate of prefectures that produce product k . μ_t is the year fixed effect. Therefore, Equation K2 stacks all years to estimate the associations between trade shocks and predetermined covariates. The regression is weighted by $\sum_i s_{ik}$. Standard errors are clustered at the 2-digit HS section level to account for correlated disturbances of products within the same sector. The coefficient of interest is β_1 . If β_1 is close to zero, it suggests that g_{kt} is not distributed in a way that may relate to differential trends of labor unrest.

Table K1 reports the results for balance tests. Covariates considered here are the same as those in Table 2 when we conduct the balance test for reform status $Reform_i$.²⁰ In Panel A, we consider trends in variables that may influence labor unrest before the start of our sample. In Panel B, we consider some baseline characteristics. We see all estimates of β_1 are statistically insignificant, supporting that $TradeShock_{it}$ can be viewed as quasi-exogenous triggers of labor unrest.

²⁰However, we are unable to examine the pre-trend in labor unrest, because the starting year of CLB is 2011.

Table K1. Balance Tests for Product-Level Trade Shocks

Dependent	Coef.	SE
Panel A: Pretrends		
$\Delta \text{Log population}_{t-1}$	0.094	(0.223)
$\Delta \text{Log GDP}_{t-1}$	0.710	(0.593)
$\Delta \text{Log total expenditure}_{t-1}$	0.526	(0.426)
$\Delta \text{Log expenditure on social security}_{t-1}$	-1.718	(1.403)
$\Delta \text{Log expenditure on public security}_{t-1}$	1.117	(0.800)
Panel B: Predetermined characteristics		
Share of males	-0.144	(0.123)
Share of migrants	-2.081	(2.072)
Share of construction workers	0.100	(0.228)
Share of manufacturing workers	-2.130	(1.992)
Share of transportation workers	0.129	(0.165)
Share of internet users	-0.135	(0.820)

Note: This table presents balance tests for product-level trade shocks, following [Borusyak et al. \(2022\)](#). Each row represents a regression of the predetermined variable, transformed to the product level, on the product-level shock (see Equation K2). The sample includes 4,374 six-digit HS products and 9 years between 2011 and 2019. For readability, all estimated coefficients are multiplied by 1,000,000. Standard errors are clustered at the 2-digit HS section level ($N = 93$).

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

K.2 Zero Stage: Effects of Origin Trade Shocks on Outmigration

To better understand this source of variation, consider the following “zero-stage” equation:

$$\Pr(Outmigration_{jodt} | \mathbf{W}_{jodt}) = \beta \cdot TradeShock_{ot} + \lambda_o + \mu_t, \quad t \in \{2014, 2015\}. \quad (K3)$$

$Outmigration_{jodt}$ is a dummy variable that equals one if migrant j , who was from origin o and lived in destination d in 2010, had left d by year t . $TradeShock_{ot}$ is the trade shock to origin o in year t , as defined in Equation 15. Since $Outmigration_{jod,2014}$ captures all migration decisions from the end of 2010 to the end of 2014, we let $TradeShock_{o,2014}$ be the average trade shock between 2011–2014, i.e., $\frac{1}{4} \sum_{t=2011}^{2014} TradeShock_{ot}$. λ_o and μ_t are origin and year fixed effects, respectively.

Table K2 presents the estimation results. We use the rural migrants sample.²¹ Column (1) is a minimal specification, showing that a \$1,000 increase in exports per worker at origins leads to a 1.69 percentage points increase in the probability of outmigration. This is consistent with the idea that better home economic conditions “pull” migrants back. In Column (2), we further control for province-by-year fixed effects, which yields a larger estimated effect of 3.1 percentage points. Column (3) shows that, interestingly, the destination trade shock has a weak effect on outmigration. However, it has an expected negative sign, suggesting that unfavorable destination conditions “push” migrants out.

Table K2. The Effects of Origin Trade Shocks on Outmigration

	Outmigration from the 2010 residing prefecture		
	(1)	(2)	(3)
Origin trade shock _{ot}	0.0169*** (0.0040)	0.0310*** (0.0048)	0.0346*** (0.0050)
Destination trade shock _{dt}			-0.0002 (0.0014)
Sample	Rural migrants	Rural migrants	Rural migrants
Origin prefecture FE	Yes	Yes	Yes
Destination prefecture FE			Yes
Year FE	Yes		
Origin province × year FE		Yes	Yes
Destination province × year FE			Yes
Observations	58,647	58,647	58,647

Note: This table reports the effects of origin trade shocks on outmigration. Standard errors clustered by origin and destination are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

²¹Using urban migrants or all migrants yields similar patterns. Results are available upon request.

K.3 IV Validity: Balance Tests for Origin Trade Shocks

Given that the instrument Z_i is a shift-share variable, we may test its validity using the same approach in Appendix K.1. To operationalize this, rewrite Z_i :

$$Z_i = \sum_h s_{h \rightarrow i} \times \text{TradeShock}_h \quad (\text{K4})$$

$$= \sum_h s_{h \rightarrow i} \times \left(\sum_k s_{hk} g_k \right) \quad (\text{K5})$$

$$= \sum_k \left(\sum_h s_{h \rightarrow i} s_{hk} \right) g_k \quad (\text{K6})$$

$$\equiv \sum_k \tilde{s}_{ik} g_k. \quad (\text{K7})$$

$\tilde{s}_{ik} \equiv \sum_h s_{h \rightarrow i} s_{hk}$ captures origin production specialization of an average migrant in prefecture i .

The excludability of Z_i follows from the quasi-exogeneity of \tilde{g}_k . In other words, one needs to assume that prefectures with differential odds of labor unrest do not systematically receive migrants from origins specializing in products with high fluctuations in global demand. We can conduct balance tests using the following regression model:

$$\tilde{q}_k = \beta_0 + \beta_1 \tilde{g}_k + \nu_k. \quad (\text{K8})$$

$\tilde{q}_k = \sum_i \frac{\tilde{s}_{ik}}{\sum_i \tilde{s}_{ik}} v_i$. v_i is a covariate of recipient prefecture i , thus, \tilde{q}_k captures the \tilde{s}_{ik} -weighted average covariate of prefectures that receive migrants from regions producing product k . The regression is weighted by $\sum_i \tilde{s}_{ik}$. Standard errors are clustered at the 2-digit HS section level to account for correlated disturbances of products within the same sector. The coefficient of interest is β_1 . If β_1 is close to zero, it suggests that \tilde{g}_k is not distributed in a way that may relate to trends of labor unrest in migrants' destinations.

Table K3 reports the results for balance tests. Covariates considered here are the same as those in Table 2 when we conduct the balance test for reform status Reform_i . In Panel A, we consider trends in variables that may influence labor unrest before the start of our sample. In Panel B, we consider some baseline characteristics. All estimates of β_1 are statistically insignificant, indicating that Z_i can be a valid instrument that predicts outmigration without picking up unobserved determinants of labor unrest.

Table K3. Balance Tests for Product-Level Trade Shocks at Origins

Dependent	Coef.	SE
Panel A: Pretrends		
$\Delta \text{Log population}_{t-1}$	0.114	(0.085)
$\Delta \text{Log GDP}_{t-1}$	0.139	(0.113)
$\Delta \text{Log total expenditure}_{t-1}$	0.312	(0.239)
$\Delta \text{Log expenditure on social security}_{t-1}$	0.022	(0.114)
$\Delta \text{Log expenditure on public security}_{t-1}$	0.124	(0.108)
Panel B: Predetermined characteristics		
Share of males	-0.019	(0.021)
Share of migrants	0.106	(0.112)
Share of construction workers	0.028	(0.055)
Share of manufacturing workers	-0.019	(0.081)
Share of transportation workers	0.050	(0.052)
Share of internet users	0.146	(0.157)

Note: This table presents balance tests for origin-level trade shocks, following [Borusyak et al. \(2022\)](#). Each row represents a regression of the predetermined variable, transformed to the product level, on the product-level trade shock change. Standard errors are clustered at the 2-digit HS section level. For readability, all estimated coefficients are multiplied by 1,000,000.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

K.4 Robustness Checks

Controlling for Covariates. In Table K4 and Figure K1, we conduct robustness checks by controlling for destination trade shocks and population growth in 2015. If anything, it slightly accentuates the importance of the outmigration channel.

Table K4. *Hukou Reform, Outmigration, and Labor Unrest: Controlling for Covariates*

	Baseline			+ Destination trade shocks			+ Population growth		
	(1) Total effect	(2) Mediation-OLS	(3) Mediation-IV	(4) Total effect	(5) Mediation-OLS	(6) Mediation-IV	(7) Total effect	(8) Mediation-OLS	(9) Mediation-IV

Note: This table reports causal mediation analysis, controlling for destination trade shocks and population growth. The effective F statistic is calculated following Olea and Pflueger (2013). Robust standard errors are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

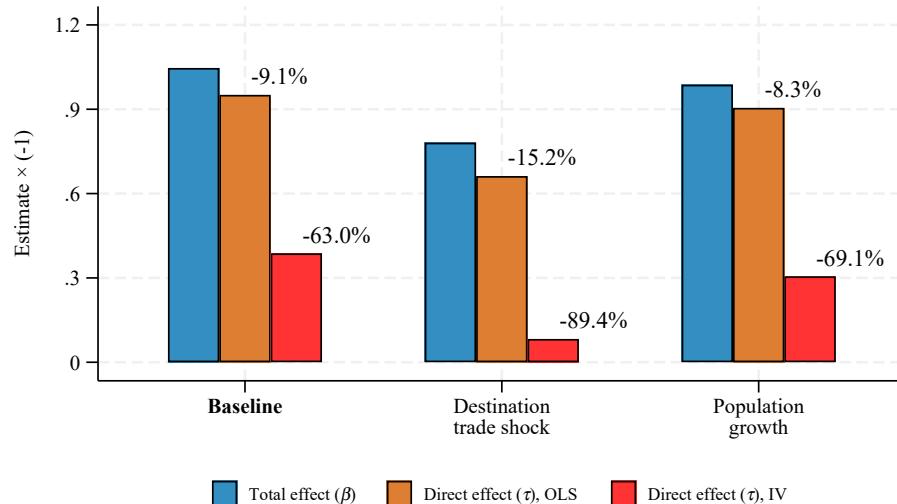

Figure K1. Mediation Visualized: Controlling for Covariates

Note: This figure examines the robustness of causal mediation results when controlling for covariates. The plots are created based upon estimates in Table K4.

Alternative IVs. Table K5 and Figure K2 report the results using alternative constructions of the IV:

1. Excluding origins within 100km;
2. Excluding origins that are regional centers (provincial capitals and four provincial-level municipalities);

3. Recentered IV, following [Borusyak and Hull \(2023\)](#):

$$Z_i^r = \sum_h s_{h \rightarrow i} \times TradeShock_{h,2015}^r. \quad (K9)$$

In this expression, $TradeShock_{h,2015}^r = \sum_k s_{hk}g_{k,2015} - \sum_k s_{hk}\bar{g}_{2015}$, where s_{hk} and $g_{k,2015}$ are defined as in Equation K1, and $\bar{g}_{2015} = \frac{1}{K} \sum_{k=1}^K g_{k,2015} \approx E(g_{k,2015})$ is the mean industry-level shock (assuming $g_{k,2015}$'s are i.i.d. distributed).

Table K5. *Hukou Reform, Outmigration, and Labor Unrest: Alternative IVs*

Observations	287	287	287	287	287	286	287	287	287	287	287	287

Note: This table reports causal mediation analysis that quantifies the importance of the settlement intentions mechanism, as captured by the outmigration rate. Columns (1)–(3) present the baseline results for ease of comparison. Columns (4)–(6) use an IV constructed using origins that are 100km away. Columns (7)–(9) use an IV constructed using origins that are not regional centers (provincial capitals and four provincial-level municipalities). Columns (10)–(12) use the re-centered IV construction proposed by [Borusyak and Hull \(2023\)](#) to address potential omitted variables bias. The effective F statistic is calculated following [Olea and Pfueger \(2015\)](#). Robust standard errors clustered at the prefecture level are reported in parentheses.

* $p < 0.1$ ** $p < 0.05$ *** $p < 0.01$

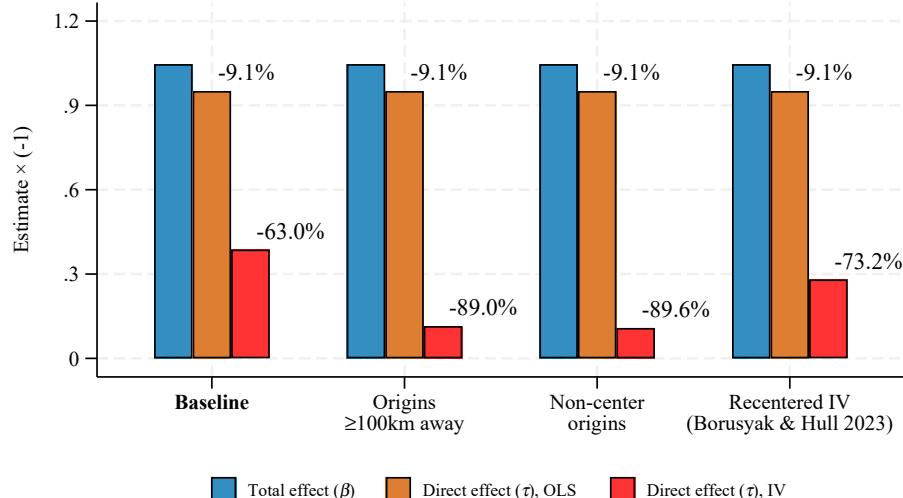

Figure K2. *Mediation Visualized: Alternative IVs*

Note: This figure examines the robustness of causal mediation results when using alternative IV constructions. The plots are created based upon estimates in Table K5.

Sensitivity to Violations of the Exclusion Restriction. Uncontrolled confounders can lead to violations of the exclusion restriction, but it is challenging to find proxies for all possible confounding factors. To examine the sensitivity of our 2SLS estimate of γ in Equation 13 to violations of the exclusion restriction, we use the methodology developed by [Conley et al. \(2012\)](#). This approach allows the IV, Z_i , to directly enter the second stage of the model (Equation 13) with a coefficient of ψ , which measures the extent to which the exclusion restriction is violated and is set by the researcher.

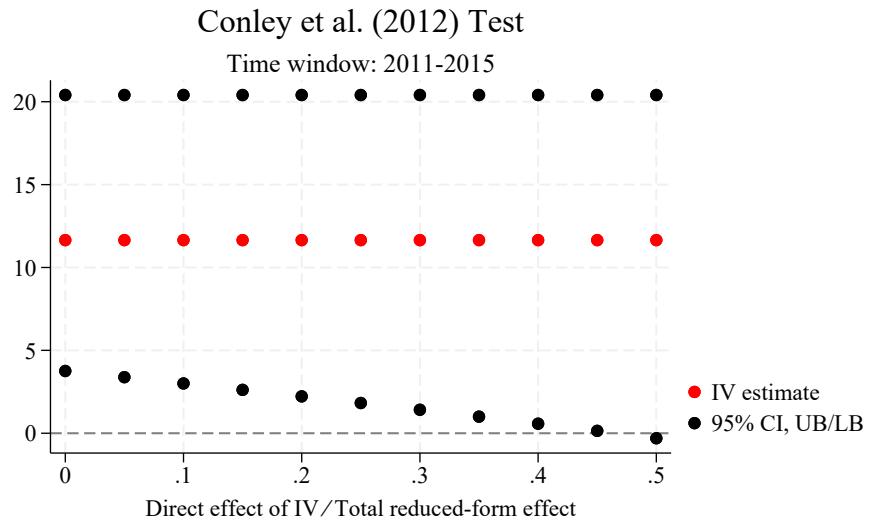

Figure K3. Conley et al. (2012) Test

Note: This figure reports the test proposed by Conley et al. (2012). This test allows the IV to have a direct effect on the outcome, and on that basis, it examines if the IV estimate remains statistically significant. In this figure, we plot the confidence interval of the IV estimate against the hypothesized direct effect of the IV (relative to the total reduced effect of the IV).

We test whether instrumented outmigration still has a significant effect on labor unrest for different values of ψ . Since we find that outmigration has a positive effect, violations of the exclusion restriction are problematic only when ψ is positive. We look at the largest positive value of ψ such that the resultant 2SLS estimate $\hat{\gamma}$ is still significant at the 5% level. This value is denoted by $\bar{\psi}$, and it is scaled by Z_i 's reduced-form effect on labor unrest, ψ_{RF} . The ratio $\bar{\psi}/\psi_{RF}$ represents the maximum hypothetical violation of the exclusion restriction that can be allowed while the 2SLS estimate $\hat{\gamma}$ remains statistically significant. A higher $\bar{\psi}/\psi_{RF}$ indicates stronger resilience of the IV to violations of the exclusion restriction.

Figure K3 reports the results, where we plot the 95% confidence interval of the 2SLS estimate $\hat{\gamma}$ against $\bar{\psi}/\psi_{RF}$. It shows that $\bar{\psi}/\psi_{RF} = 0.5$. These results indicate that unobserved confounders must contribute to at least 40–50 percent of Z_i 's reduced effect in order to accept a null effect of outmigration on labor unrest. We believe this fraction is unrealistically high, and our instrumentation procedure should be valid.²²

²²Conley et al. (2012) do not provide a rule-of-thumb cutoff for $\bar{\psi}/\psi_{RF}$. However, using Conley et al. (2012)'s approach, researchers have demonstrated the robustness of their 2SLS estimates given the following $\bar{\psi}/\psi_{RF}$ ratios: 0.3 in Fatás and Mihov (2013) and 0.46 in Bentzen et al. (2017).

K.5 Sensitivity Test Under the General Framework

By Proposition J3, we examine how much \widehat{AIE} changes when $\rho_{\phi\gamma}$ and $\rho_{\gamma\pi}$ deviate from zero. We expect that $\gamma_i \geq 0$ and $\pi_i \leq 0$, i.e., a high outmigration rate (low settlement intention) universally increases unrest, and the *hukou* reform reduces outmigration from the destination (or raises settlement intentions). Then, we consider $\rho_{\phi\gamma} > 0$ and $\rho_{\gamma\pi} > 0$, so that \widehat{AIE} corrects the overestimation of AIE by \widehat{AIE} .

Specifically, we look at the share of total effect explained by the proposed mechanism: $ShareExplained = \widehat{AIE}/\hat{\beta}$, for different pairs of $\rho_{\phi\gamma} > 0$ and $\rho_{\gamma\pi} > 0$. If $ShareExplained$ drops significantly when only small values $\rho_{\phi\gamma}$ and $\rho_{\gamma\pi}$ are imposed, then it is not reliable to maintain our previous conclusion under constant γ_i , stating heightened settlement intentions as an important mechanism linking the *hukou* reform to decreased labor unrest.

Figure K4 reports the results of our sensitivity test based on Proposition J3. We see that, when $\rho_{\phi\gamma} = 0$ and $\rho_{\gamma\pi} = 0$, which is true when γ_i is constant, we obtain the highest $ShareExplained$, 63 percent, as we have seen previously. Overall, $ShareExplained$ is more sensitive to bias 1 (IV bias): *ceteris paribus*, $ShareExplained$ drops more quickly when $\rho_{\phi\gamma}$ increases than when $\rho_{\gamma\pi}$ increases. For the most extreme case $\rho_{\gamma\pi} = 0$ but $\rho_{\phi\gamma} = 1$, we see that heightened settlement intentions can still explain at least 15 percent of the *hukou* reform's total effect on decreasing labor unrest. A magnitude of 25 percent can be maintained if we allow for moderate severity of both bias 1 and bias 2, e.g., with $\rho_{\gamma\pi} = \rho_{\phi\gamma} = 0.5$.

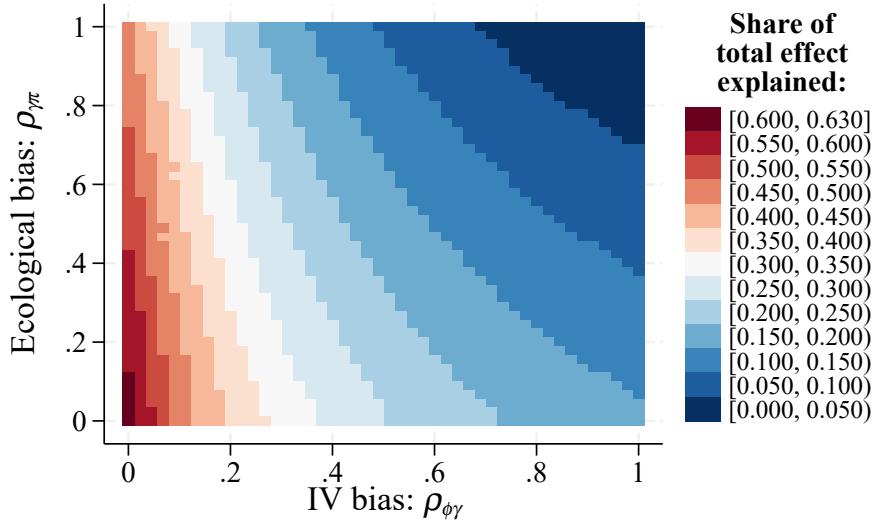

Figure K4. Sensitivity Test for Causal Mediation Under General Framework

Note: This figure presents the share of total effect explained by the settlement intentions mechanism, calculated as $\widehat{AIE}/\hat{\beta}$, for each given combination of $\rho_{\phi\gamma}$ and $\rho_{\gamma\pi}$.

L Replication of An et al. (2024)

In this section, we replicate the main results in [An et al. \(2024\)](#): the effects of *hukou* reform on workforce participation, wages, and access to social security (ASS), which we also investigate in Table 7. They also use the CMDS data, and their findings are: (i) the reform has no effect on migrants' workforce participation; (ii) the reform significantly lowers wages; and (iii) the reform reduces ASS. However, we do not find (ii) and (iii). We show how this discrepancy arises.

There are two major differences between their and our empirical implementations.

1. *Reform Status Definition.* To measure reform status, we use the total urban population that includes both natives and migrants from the Urban Construction Yearbook (UCSY), whereas [An et al. \(2024\)](#) use only the native urban population.
2. *Identification Strategy.* [An et al. \(2024\)](#) implement a DiD design as specified by Equation 1 that in essence compares . In contrast, our strategy, as given by Equation 2, combines DiD and RD designs (DiDC).

Table L1 explores how results change due to these decisions. To avoid other sources of differences, e.g., sample construction, we produce these results using the sample in [An et al. \(2024\)](#)'s replication package. Panel A adopts the [An et al. \(2024\)](#)'s definition of reform status, whereas Panel A uses our definition. Columns (1)–(3) report DiD estimates, and Columns (4)–(6) report the DiDC estimates. Clearly, different definitions of reform status do change the reform and non-reform groups. We, by using the total urban population, define 10 fewer prefectures as reform ones. Nonetheless, different definitions of reform status do not change the results markedly. The major change is due to the identification strategy. Once flexible polynomial functions of log urban population are included, there are no longer discernible effects of the *hukou* reform on wages and ASS. This pattern also appears when we use our own working sample (see Table L2).

The DiDC strategy may produce cleaner, more reliable results than a DiD design as it flexibly controls heterogeneity due to urban sizes. Also, we find it difficult to reconcile the *hukou* reform's negative effects on wages and ASS. [An et al. \(2024\)](#) interpret them as reflecting that the reform has induced labor inflow and thus reduces wages and imposes pressure on the local social security system. However, as we show in Appendix G.5, the reform in fact has at most a zero effect on population. Taken together, we argue that the *hukou* reform does not affect wages and ASS much.

Table L1. Replicating Main Results of An et al. (2024)

	(1) Working	(2) Log wage	(3) ASS	(4) Working	(5) Log wage	(6) ASS
